PREFACE TO THIRD EDITION

The former editions of this handbook have been so well received that the publishers, Messrs. John Wiley and Sons, Inc., suggested the possibility of increasing its usefulness by the addition of material relating to thermodynamics and to electrical engineering. For the preparation of a section on heat engineering, Professor G. A. Goodenough, of the University of Illinois, was selected, while Professor H. H. Higbie, of the University of Michigan, was chosen to prepare a section on electrical engineering. These two new sections and their related tables constitute the principal addition which has been made to the former edition.

L. A. W.

NITRO, W. VA., May, 1918.

PREFACE TO SECOND EDITION.

In preparing the second edition, the errors which have been discovered in the previous edition have been corrected, revisions and alterations have been made throughout the work, and new material has been added, including sections on hydraulics and reinforced concrete, and a table of conversion factors.

L. A. W.

URBANA, ILL., April, 1915.

This handpook is intended as a reference book, for the use of those who have studied or are studying the branches of mathematics usually taught in engineering courses. It is not intended for a text book, and does not, therefore, attempt to prove many of the formulæ which are given.

Most of the material in this book was obtained from the following sources: algebra from Hall & Knight's Algebra (Macmillan Co.); trigonometry from Bowser's Trigonometry; analytic geometry from Candy's Analytic Geometry: calculus from Taylor's Differential and Integral Calculus: theoretical mechanics from Church's Mechanics of Engineering: and mechanics of materials from Merriman's Mechanics of Materials; to all of which the writer is very much indebted and from all these Authors he has received permission to use the material. The reader is referred to these works for the proof and explanation of the various formulæ.

L. A. W.

Tucson, Ariz., March, 1908.

PREFACE TO FIRST EDITION WITH TABLES

In this edition tables of logarithms of numbers, natural and logarithmic sines and cosines, and natural and logarithmic tangents and cotangents have been added to facilitate. the solution of problems.

L. A. W.

Tucson, Ariz., September, 1909.

ALGEBRA.

EXPONENTS AND LOGARITHMS

If
$$a^m = b$$
, $m = \log_a b$. $a^m \cdot a^n = a^{m+n}$,
 $\therefore \log (x \cdot y) = \log x + \log y$. $a^n \div a^n = a^{m-n}$,
 $\therefore \log (x \div y) = \log x - \log y$. $(a^m)^2 = a^m \cdot a^m = a^{2m}$, $\therefore \log x^2 = 2 \cdot \log x$.
 $(a^m)^n = a^m \cdot n$, $\therefore \log x^n = n \cdot \log x$.
 $a^0 = 1$, $\therefore \log (1) = 0$.

For common logarithms the base is 10; log 10 = 1, log 100 = 2, log 1000 = 3, etc., or for any number between 1 and 10, the logarithm will have a value between 0 and 1, and may be found in a table of logarithms. The value of the logarithm of any number may be obtained by adding the proper integer to the proper value obtained from the tables. For example,

$$\log (451.7) = \log (4.517 \times 100)$$

$$= \log 4.517 + \log 100$$

$$= 0.65485 + 2$$

$$= 2.65485.$$

It may be observed that the integral part of the logarithm, called the characteristic, indicates the location of the decimal point of the number; and that the decimal portion of the logarithm, called the mantissa, determines the sequence of significant figures.

For a number less than unity, the logarithm is negative, but since the tables contain only positive values, the logarithm for such a number is ordinarily used in the form of a positive mantissa with a negative characteristic. For the purpose of involution or evolution the

logarithm may well be used in the negative form. For example,

$$\begin{array}{l} \log \left(0.04517\right) = \log \left(4.517 \div 100\right) \\ = \log 4.517 - \log 100 \\ = +0.65485 - 2 \\ (\text{or} \qquad = +8.65485 - 10) \\ = -1.34515. \end{array}$$

(The logarithm is usually written $\overline{2}.65485$.) $\log (0.04517)^{1.6} = (1.6) \cdot \log (0.04517)$ $= (1.6) \cdot (-1.34515)$ = -2.15224 = +0.84776 - 3 $= \log (0.007043)$,

 $\therefore (0.04517)^{1.6} = 0.007043.$

The base of the natural system of logarithms is

$$e = 1 + 1 + \frac{1}{2} + \frac{1}{2} + \frac{1}{4} + \frac{1}{4} + \frac{1}{5} + \cdots = 2.7182818284.$$

The cologarithm of a number is the logarithm of its reciprocal. $Log(\frac{1}{x}) = 0 - log x$.

To transform a logarithm from base e to base 10, multiply by $\log_{10} e$.

Log₁₀
$$e = 0.43429448$$
.
Log_e 10 = 2.30258509.
Log₁₀ $e = \frac{1}{\log_e 10}$.

PROPORTION.

If
$$a:b::c:d$$
,
$$\frac{a}{b} = \frac{c}{d}, \text{ or } \frac{b}{a} = \frac{d}{c},$$

$$ad = bc, \quad \frac{a+b}{b} = \frac{c+d}{d},$$

$$\frac{a-b}{b} = \frac{c-d}{d}, \quad \frac{a+b}{a-b} = \frac{c+d}{c-d}.$$

ARITHMETICAL PROGRESSION.

$$a, a+d, a+2d, \ldots$$

Last term, L = a + (n-1) d. Sum of terms,

 $S = \frac{n}{2}(a+L) = \frac{n}{2}[2a+(n-1)d].$

GEOMETRICAL PROGRESSION.

$$a, ar, ar^2, ar^3, \ldots$$

Last term, $L = ar^{n-1}$. Geometric mean, $M = \sqrt{ab}$.

Sum,
$$S = \frac{a(r^n - 1)}{r - 1}$$

= $\frac{a(1 - r^n)}{1 - r} = \frac{rL - a}{r - 1}$.

For an infinite geometrical series, the sum $S = \frac{a}{1-a}$ to infinity is

HARMONIC PROGRESSION.

a, b, c are in harmonic progression if

$$\frac{a}{c} = \frac{a-b}{b-c},$$

or if $\frac{1}{a}$, $\frac{1}{b}$, $\frac{1}{c}$ are in arithmetical progression.

PERMUTATIONS AND COMBINATIONS.

ab and ba are two permutations but only one combination.

The number of permutations possible of n things taken r at a time is

$${}^{n}P_{r} = n (n-1) (n-2) \dots (n-r+1).$$

$${}^{n}P_{n} = \lfloor \underline{n} \rfloor.$$

$$(\lfloor \underline{n} = 1 \times 2 \times 3 \times 4 \cdots \times n).$$

$${}^{n}C_{r} = \frac{{}^{n}P_{r}}{\lfloor \underline{r} \rfloor} = \frac{\lfloor \underline{n} \rfloor}{\lfloor \underline{r} \rfloor (\underline{n-r})} = {}^{n}C_{n-r}.$$

BINOMIAL THEOREM.

$$(a+b)^{n} = a^{n} + n \cdot a^{n-1} \cdot b + \frac{n \cdot (n-1)}{2} \cdot a^{n-2} \cdot b^{2} + \frac{n \cdot (n-1) \cdot (n-2)}{2} \cdot a^{n-3} \cdot b^{3} + \cdots \cdots$$

SERIES.

- 1. An infinite series in which the terms are alternately positive and negative is convergent if each term is numerically less than the preceding term.
- 2. An infinite series in which all the terms are of the same sign is divergent if each term is greater than some finite quantity, however small.
- 3. An infinite series is convergent if from and after some fixed term the ratio of each term to the preceding term is numerically less than unity.
- 4. An infinite series in which all the terms are of the same sign is divergent if from and after some fixed term the ratio of each term to the preceding term is greater than unity, or is equal to unity.
- 5. If there are two infinite series in each of which all the terms are positive, and if the ratio of the corresponding terms in the two series is always finite, the two series are both convergent, or both divergent.

DETERMINANTS.

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = a_1b_2 - a_2b_1.$$

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = a_1 \cdot b_2 \cdot c_3 + a_2 \cdot b_3 \cdot c_1 + a_3 \cdot b_1 \cdot c_2 - a_1 \cdot b_3 \cdot c_2 - a_2 \cdot b_1 \cdot c_3 - a_3 \cdot b_2 \cdot c_1.$$

then

$$\begin{array}{c|ccccc}
x & = & -y & = & z & = & -1 \\
\hline
b_1c_1d_1 & & & & & & & & & & & \\
b_2c_2d_2 & & & & & & & & & & & \\
b_3c_3d_3 & & & & & & & & & & & & \\
\end{array}$$

QUADRATIC EQUATIONS.

$$ax^{2} + bx + c = 0$$

$$x = \frac{-b \pm \sqrt{b^{2} - 4 ac}}{2 a}.$$

CUBIC EQUATIONS.*

First Form.

$$x^3 + bx + c = 0. (1)$$

Let
$$x = y - \frac{b}{3y} \tag{2}$$

or
$$y^6 + cy^3 - \frac{b^3}{27} = 0,$$
 (3)

whence,
$$\mathbf{v}^3 = -\frac{c}{2} \pm \sqrt{\frac{c^2 + b^3}{4 + 27}}$$
 (4)

from which x may be obtained by substituting the value of y in equation (2).

Second Form.

$$x^3 + ax^2 + c = 0. (5)$$

Let
$$x = 1/z$$
 (6)

or
$$z^3 + \frac{a}{c}z + \frac{1}{c} = 0,$$
 (7)

which may be solved by equations (1) to (4) and the value of x may then be obtained by equation (6).

Third Form.

$$x^3 + ax^2 + bx + c = 0. (8)$$

Let
$$x = z - \frac{a}{3}, \qquad (9)$$

^{*} The equations here used follow the method given in Wells' University Algebra.

which, when substituted in equation (8), will give an equation of the first form, the solution of which will give the value of z, from which x may be obtained by equation (9).

HIGHER EQUATIONS.*

For higher algebraic equations, an approximate numerical solution can be obtained by the method of double position, as follows:

$$f(x) = x^n + ax^{n-1} + bx^{n-2} \cdot \cdot \cdot = 0.$$
 (1)

By trial find two numbers one of which when substituted for x makes f(x) positive, and the other when substituted for x makes f(x) negative. Let a and b be the two numbers, and let A and B be the respective corresponding values of f(x). Then, approximately,

$$A: B = (x - a): (x - b)$$
 (2)

or $x = a + \frac{A(b-a)}{A-B}.$ (3)

GRAPHICAL SOLUTION OF EQUATIONS.

To determine the value of x in any equation, f(x) = 0, let y = f(x) and compute the values of y for a number of assumed values of x. Using the values of x and y as coördinates, plot the graph of the equation, y = f(x), from which the value of x which will make f(x) become zero can be observed.

For two simultaneous equations, involving two unknowns, the graph of each equation may be plotted with reference to one set of axes. If the two graphs intersect, the points of intersection will have coördinates which are the values of the two unknowns. If the graphs can not be made to intersect, there are no real values of x and y which are common to both equations.

^{*} See Wells' University Algebra.

ELEC.

For any equation, y = f(x), the logarithms of x and y may be plotted instead of the quantities themselves, producing the logarithmic graph of the equation. Logarithmic graphs are particularly useful for equations of the form, $y = ax^b$, for which the graphs are straight lines.

TRIGONOMETRY.

Fig. 1.

Radius = 1.

 $AB = \sin \theta$.

HYPERBOLIC FUNCTIONS.

For the equilateral hyperbola, $x^2 - y^2 = a^2$, a series of functions can be obtained, analogous to the circular functions.

Let x, y be the coördinates of any point P (Fig. 4), let the radius OP = r, let v = the arc MP divided by r,

and let OM = a.

Then, $\sinh u = y/a$. $\cosh u = x/a$. $\tanh u = y/x$. $\coth u = x/y$. $\operatorname{sech} u = a/x$. $\operatorname{cosech} u = a/y$.

THE STRAIGHT LINE.

Equations of Straight Line. An equation of the first degree containing but two variables can always be represented by a straight line.

The equation of the straight line may assume the following forms, for the rectangular system of coördinates.

$$Ax + By + C = 0 \quad . \quad . \quad (1)$$

$$y = mx + k \dots \dots (2)$$

in which m is the value of the tangent of the angle which the line makes with the X-axis, and k is the intercept on the Y-axis between the line and the X-axis.

$$y - y' = A (x - x') \dots$$
 (3)

in which x', y' are the coördinates of a point of the line, and A is a constant.

$$y-y'=\frac{y'-y''}{x'-x''}(x-x')$$
 . . . (4)

in which x', y' and x'', y'' are the coördinates of two points of the line.

Fig.9.

The polar equation of a straight line is

$$\rho \cdot \cos \left(\theta - \alpha\right) = k \quad (5)$$

where k is the length of the normal ON.

Distance between Two Points. The distance between two points, x', y' and x'', y'', is equal to

$$\sqrt{(x'-x'')^2+(y'-y'')^2}$$

The distance between two points, ρ_1 , θ_1 , and ρ_2 , θ_2 , is equal to

$$\sqrt{\rho_1^2+\rho_2^2-2\,\rho_1\cdot\rho_2\cdot\cos\,(\theta_1-\theta_2)}.$$

Angle between Two Lines. The angle between two lines, y = m'x + k' and y = m''x + k'',

is the difference between the two angles whose tangents are m' and m''.

Area of Triangle. The area of the triangle whose vertices are (x_1, y_1) , (x_2, y_2) , and (x_3, y_3) is equal to

$$\frac{1}{2} \cdot \left| \begin{array}{c} x_1 \ y_1 \ 1 \\ x_2 \ y_2 \ 1 \\ x_3 \ y_3 \ 1 \end{array} \right| \cdot$$

THE CIRCLE.

The most general equation of the circle, for rectangular coördinates, is

$$(x-a)^2 + (y-b)^2 = R^2$$
,

in which a, b are the coördinates of the center of the circle, and R is the radius.

The following are special equations of the circle for rectangular and polar systems of coördinates.

Fig. 11.

$$x^2 = 2 Ry - y^2.$$

$$\rho = 2 R \cdot \sin \theta.$$

Fig. 10.

$$y^2 = 2 Rx - x^2.$$

$$\rho = 2 R \cdot \cos \theta.$$

Fig. 12

THE PARABOLA.

In Fig. 13, F is the focus, OF = OD = a, and L-L is the latus rectum = 4a.

Eccentricity,
$$e = \frac{FP}{PQ} = 1$$
.

If the Y-axis coincides with the directrix, DM, then

$$y^2 = 4 a (x - a)$$
.

If the Y-axis coincides with ON, passing through the vertex, then

$$y^2 = 4 \ ax.$$

For a symmetrical segment of a parabola, the area of the segment is exactly two-thirds of the area of the enclosing rectangle.

THE ELLIPSE.

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

Fig. 14.

F, F are foci.

Eccentricity, e < 1.

The area of the ellipse is equal to πab .

Fig. 15.

A - A = principal hyperbola. B - B = conjugate hyperbola. c - c = asymptote.

Principal hyperbola: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$.

Asymptotes: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 0.$

Conjugate hyperbola: $\frac{x^2}{a^2} - \frac{y^2}{b^2} = -1$.

When referred to the asymptotes as axes, the equations become:

Principal hyperbola: $xy = \frac{a^2 + b^2}{4}$.

Conjugate hyperbola: $xy = -\left(\frac{a^2 + b^2}{4}\right)$

D - D is the directrix.

F, F are foci.

$$\frac{FP}{PQ}=e>1.$$

For the equilateral hyperbola, a = b, for which the equation of the principal hyperbola becomes $x^2 - y^2 = a^2$.

THE LOGARITHMIC SPIRAL.

$$\log \rho = k \cdot \theta.$$

If k = 1, and logarithms to the base a are employed, then the equation may be written

$$\rho = a^{\theta}$$
.

$$y = \frac{a}{2} \left(e^{\frac{x}{a}} + e^{-\frac{x}{a}} \right).$$

THE CUBIC PARABOLA.

 $y = kx^3$.

THE SPHERE.

R = radius, and D = diameter. For the origin at the center,

$$x^2+y^2+z^2=R^2$$
.

Area of surface $= 4 \pi R^2 = \pi D^2$.

Volume $= \frac{4}{3} \pi R^3 = \frac{1}{6} \pi D^3$.

CONES.

The equation of the cone generated by the line, z = mx + c, rotated about the Z-axis, is

$$x^2 + y^2 = \frac{(z-c)^2}{m^2}$$
.

The volume of a cone is $\frac{1}{3}$ Ah, where A is the area of the base, and h is the altitude.

OBLATE SPHEROIDS.

The equation of the oblate spheroid generated by the ellipse, $\frac{x^2}{a^2} + \frac{z^2}{b^2} = 1$, rotated about its minor axis, is

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} + \frac{z^2}{b^2} = 1.$$

PROLATE SPHEROIDS.

The equation of the prolate spheroid generated by the ellipse, $\frac{x^2}{b^2} + \frac{z^2}{a^2} = 1$, rotated about its major axis, is

$$\frac{x^2}{b^2} + \frac{y^2}{b^2} + \frac{z^2}{a^2} = 1.$$

HYPERBOLOIDS.

The equation of the hyperboloid of one nappe, generated by the hyperbola, $\frac{x^2}{a^2} - \frac{z^2}{b^2} = 1$, rotated about its conjugate axis, is

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{b^2} = 1.$$

The equation of the hyperboloid of two nappes, generated by the hyperbola, $\frac{x^2}{a^2} - \frac{z^2}{b^2} = 1$, rotated about its transverse axis, is

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{b^2} = 1.$$

THE PARABOLOID.

The equation of the paraboloid of revolution generated by the parabola, $x^2 = 4 az$, rotated about its axis, is

$$x^2 + y^2 = 4 az$$

GENERAL EQUATION_OF CONIC SECTION.

The general equation of any conic section, for which the Y-axis coincides with the directrix and the X-axis passes through the foci normal to the directrix, is

$$(x-k)^2+y^2=e^2x^2$$
,

where k is the distance from the directrix to the focus, and e is the eccentricity.

DIFFERENTIAL CALCULUS.

Variables will be represented by u, v, x, y, and z, and constants by a, b, m, and n.

D will be used as the sign for the derivative, and d as the sign for the differential.

 $\sin^{-1} x = \text{angle whose sine is } x.$

$$D(fx) = \frac{d(fx)}{dx}$$

$$D_x y = \frac{dy}{dx}.$$

:. To obtain the derivative of any funcsion, drop the differential of the variable from the differential of the function.

$$D_x(fy) = D_y(fy) \cdot D_x y.$$

$$da=0.$$

$$d(av) = a \cdot dv.$$

$$d(u+v+x) = du+dv+dx.$$

$$d(x \cdot y) = y \cdot dx + x \cdot dy.$$

$$d(u \cdot v \cdot x \cdot y \dots) = (v \cdot x \cdot y \dots) du + (u \cdot x \cdot y \dots) dx + (u \cdot v \cdot$$

$$(u \cdot v \cdot x \dots) dy + \dots$$

$$d\left(\log_e u\right) = \frac{du}{u}.$$

$$d\left(\log_a u\right) = \log_a e \cdot \frac{du}{u}.$$

$$d\left(\frac{x}{y}\right) = \frac{y \cdot dx - x \cdot dy}{y^2}.$$

$$dx^a = a \cdot x^{a-1} \cdot dx.$$

$$d\sqrt{x} = \frac{dx}{2\sqrt{x}}$$
.

$$d (\sin x) = \cos x \cdot dx.$$

$$d(\cos x) = -\sin x \cdot dx.$$

$$d (\tan x) = \sec^2 x \cdot dx.$$

$$d(\cot x) = -\csc^2 x \cdot dx.$$

$$d (\sec x) = \sec x \cdot \tan x \cdot dx$$
.

$$d (\csc x) = -\csc x \cdot \cot x \cdot dx.$$

$$d \text{ (vers } x) = d \text{ (}1 - \cos x\text{)} = +\sin x \cdot dx.$$

$$d (\operatorname{covers} x) = d (1 - \sin x) = -\cos x \cdot dx$$
.

$$d (\sin^{-1} x) = dx / \sqrt{1 - x^2}$$
.

$$d(\cos^{-1}x) = -dx/\sqrt{1-x^2}$$
.

$$d(\tan^{-1}x) = dx/(1+x^2)$$
.

$$d(\cot^{-1} x) = -dx/(1+x^2)$$
.

$$d (\sec^{-1} x) = dx / (x \sqrt{x^2 - 1}).$$

$$d \text{ (vers}^{-1} x) = dx / \sqrt{2 x - x^2}$$
.

$$d \text{ (covers}^{-1} x) = -dx/\sqrt{2 x-x^2}$$
.

To differentiate a function:

- 1. Find the value of the increment of the function in terms of the increments of its variables.
- 2. Consider the increments to be infinitesimals, and in all sums drop the infinitesimals of higher order than the first, and in the

remaining terms substitute differentials fo increments.

For the maximum value of a function the first derivative is zero, and the second derivative is negative.

For the *minimum* value of a function the first derivative is zero, and the second derivative is positive.

If $\frac{Fx}{fx}$ assumes the form $\frac{0}{0}$, then

$$\frac{Fx}{fx} = \frac{D(Fx)}{D(fx)}.$$

Taylor's theorem is

$$f(x+h) = fx + h \cdot D(fx) + \frac{h^2}{2!} \cdot D^2(fx) + \cdots$$

$$\cdots + \frac{h^n}{n!} \cdot D^n (fx).$$

$$fx = f(0+x) = f(0) + x \cdot D(f0) + \frac{x^2}{12} \cdot D^2(f0) + \cdots$$

The radius of curvature for a curve, y = fx, is

$$R = \frac{ds}{d\alpha} = \frac{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{\frac{2}{3}}}{\frac{d^2y}{(dx)^2}} = \frac{(ds)^3}{dx \cdot d^2y}.$$

STATICS.

Equilibrium of Forces.

Concurrent Forces in Equilibrium in One Plane.

Non-concurrent Forces in Equilibrium in One Plane.

If three forces are in equilibrium they must be concurrent or parallel.

If a system of non-concurrent forces in space is in equilibrium, the plane systems formed by projecting the given system upon three coördinate planes must each be in equilibrium.

A couple consists of two equal and opposite parallel forces acting on a rigid body at a fixed distance apart.

The moment of a couple is equal to the product of one force by the distance between the two forces.

Centroid of Parallel Forces.

$$R = \Sigma F.$$

$$\bar{x} = \frac{\Sigma Fx}{\Sigma F}.$$

For a variable pressure,

$$\bar{x} = \frac{\int xF \, dx}{\int F \, dx}.$$

Moment of Inertia of a Mass.

If k is a constant, equal to the density divided by g,

Fig. 27.

$$\begin{split} I_z &= \rho^2 \, dm \\ &= k \int \int \int \rho^2 \, dx \, dy \, dz \\ &= k \int \int \int \left(x^2 + y^2 \right) \, dx \, dy \, dz. \end{split}$$

Product of Inertia of an Area.

$$J = \Sigma xy \ dA = \int \int xy \ dx \ dy.$$

For the principal axes, J is zero.

Radius of Gyration. $r = \sqrt{\frac{I}{A}}$, or $r = \sqrt{\frac{I}{m}}$.

Transformation Formulæ.

$$I_x = I_{gx} + Ad^2$$
 or
$$I_x = I_{gx} + md^2.$$

$$J_{xy} = J_{c.g.} + Akh,$$

where h, k are the coördinates of the center of gravity referred to X-X and Y-Y.

 $I'_x = I_x \cos^2 \theta$ $\begin{array}{l} +I_y\sin^2\theta \\ -J_{xy}\sin^22\theta. \end{array}$ $J'_{xy} = J_{xy} \cos 2\theta$ $+\frac{1}{2}(I_x-I_y)\sin 2\theta.$

To determine the value of θ which will make X'-X' a principal axis.

 $\tan 2\theta = \frac{2J_{xy}}{I_{x}-I_{x}}.$

Ellipsoid of Inertia.

The moments of inertia about all axes through any given point of any rigid body are inversely proportional to the squares of the diameters which they intercept in an imaginary ellipsoid, whose center is given point, and whose position depends upon the distribution of the mass and the location of the given point. This ellipsoid is the ellipsoid of inertia for the body. The axes which contain the principal diameters of the ellipsoid are called the principal axes of the body for the given point.

Circle of Inertia.*

For any plane figure, lay off OX parallel to X-X

Fig. 30.

 $OA = I_x$ $OB = I_w$ $BC = J_{xy}$ $BQ = \frac{1}{2} BA,$

circle through C with center at Q.

* See Maurer's Technical Mechanics, Appendix B, or Civil Engineers' Pocket Book.

MECHANICS

CD parallel to X'-X' (Fig. 29), DE perpendicular to OX,

$$QF = EQ$$
.

Then

$$OE = I'_x$$
, and $OF = I'_y$.
 $ED = J'_{xy}$.

The principal axes for the given point are parallel to CM and CN.

J is positive above and negative below OX.

DYNAMICS.

Velocity and Acceleration.

$$v = \frac{ds}{dt}.$$

$$a = \frac{dv}{dt} = \frac{d^2s}{dt^2}.$$

Uniformly Accelerated Motion.

If a is constant.

$$v = v_0 + at.$$

$$S = v_0 t + \frac{1}{2} at^2$$

$$= \frac{v^2 - v_0^2}{2 a}$$

$$= \frac{1}{2} (v_0 + v) t.$$

$$v dv = a ds.$$

Falling Bodies.

For a body falling in a vacuum, a=g, hence

$$v = v_0 + gt.$$

$$S = v_0 t + \frac{1}{2} gt^2$$

$$= \frac{v^2 - v_0^2}{2 g}$$

$$= \frac{1}{2} (v_0 + v) t.$$

$$F = m \cdot a = \frac{W}{g} \cdot a$$
.

Direct Central Impact.

For two inelastic bodies, let

 $m_1 = \text{mass of first body.}$

 $m_2 = \text{mass of second body.}$

 v_1 = original velocity of first body.

 v_2 = original velocity of second body.

v =common velocity after impact.

Then

$$v = \frac{m_1 v_1 + m_2 v_2}{m_1 + m_2}.$$

For two elastic bodies having velocities k_1 and k_2 after impact,

$$m_1v_1+m_2v_2=m_1k_1+m_2k_2$$
.

The product of mass by its velocity is momentum.

The sum of the momenta before and after impact is constant.

Virtual Velocities.

F =force.

V = direction of motion of P. du = virtual velocity of force.

ce.

$$\frac{du}{dt}$$
 = velocity of force.

$$\frac{ds}{dt}$$
 = velocity of P .

 $F \cdot du = \text{virtual moment of force.}$

The virtual moment of a force is equal to the algebraic sum of the virtual moments of its components.

For a system of concurrent forces in equilibrium,

$$\Sigma F \cdot du = 0.$$

MECHANICS OF MATERIALS

> HY-DRAULICS

HEAT

ELEC.

TAB.

For any small displacement or motion of a rigid body in equilibrium under non-concurrent forces in a plane, with all points of the body moving parallel to this plane,

$$\Sigma F \cdot du = 0.$$

Curvilinear Motion of a Point.

$$v_{t} = \frac{ds}{dt}.$$

$$v_{t}^{2} = \left(\frac{ds}{dt}\right)^{2}$$

$$= \left(\frac{dx}{dt}\right)^{2} + \left(\frac{dy}{dt}\right)^{2}.$$

$$v_{t}^{2} = v_{x}^{2} + v_{y}^{2}.$$

$$x_{t} = \frac{dv}{dt} = \frac{d^{2}s}{dt^{2}}$$

$$= a_{x} \cos \theta + a_{y} \sin \theta.$$

$$a_{n} = a_{y} \cos \theta - a_{x} \sin \theta = \frac{v_{t}^{2}}{r},$$

where r is the radius of curvature.

$$F_n = \frac{m \cdot v_t^2}{r} \cdot F_t = m \cdot a_x \cos \theta + m \cdot a_y \sin \theta = m \cdot a_t \cdot \frac{v^2 - v_0^2}{2} = \int a_t ds.$$

Projectiles.

Neglecting the resistance of the air,

$$x = v_0 \cos \theta \cdot t.$$

$$y = v_0 \sin \theta \cdot t - \frac{1}{2} gt^2,$$
or
$$y = x \tan \theta - \frac{gx^2}{2 v_0^2 \cos^2 \theta}.$$

Horizontal range,

$$x_r = \frac{{v_0}^2}{g} \sin 2 \, \theta,$$

which is a maximum for $\theta = 45^{\circ}$.

The greatest height of ascent is

$$y_m = \frac{v_0^2}{2 g} \sin^2 \theta.$$

Translation of a Rigid Body.

$$dF_x = a_x \cdot dm.$$

$$R_x = \int a_x \cdot dm.$$

Fig. 33.

Fig. 34.

The resultant force must act in a line through the center of gravity and parallel to the direction of motion.

Rotation of a Rigid Body.

Let O be the axis of rotation.

 θ =angular space passed over by any line from O.

 α = angular acceleration.

 $\omega = \text{angular velocity.}$

Then

$$\omega = \frac{d\theta}{dt}$$
.

$$\alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2} \cdot .$$

$$\omega d\omega = \alpha d\theta$$

 ϵ = unit deformation.

Direct Stress.

For an axial tensile or compressive force, or for simple shear,

$$S = \frac{F}{A}.$$

$$\epsilon = \frac{e}{l}.$$

$$E = \frac{S}{\epsilon} = \frac{Fl}{eA}.$$

For tension or compression the deformation is measured along the axis of the member, and for shear it is measured at right angles to the axis of the member. MECHANICS OF MATERIALS

Eccentric Loads.*

Fig. 43.

Consider a section a-a perpendicular to axis of a bar, and take axes of coördinates through center of gravity.

Let x, y = co"ordinates of any point of section.

n-n = neutral axis.

v=distance of any point from line through center of gravity and parallel to neutral axis, positive toward P.

 v_0 = value of v for neutral axis.

F =force or resultant of forces acting at P.

N =component of F normal to section considered.

 S_0 = unit stress at center of gravity.

$$S_0 = \frac{N}{A}$$
.

^{*} The method here presented is taken from a paper by L. J. Johnson, M. Am. Soc. C. E., "An Analysis of General Flexure in a Straight Bar of Uniform Cross Section," Trans. Am Soc. C. E., volume LVI, p. 169, 1906.

$$S = S_0 - \frac{S_0}{v_0} \cdot v$$

$$= S_0 - \frac{S_0}{v_0} (y \cos \alpha - x \cdot \sin \alpha)$$

$$= \frac{N}{A} + \frac{N \cdot x_P (y - x \tan \alpha)}{J - I_y \tan \alpha}$$

$$= \frac{N}{A} + \frac{N \cdot y_P (y - x \tan \alpha)}{I_x - J \tan \alpha}$$

$$= \frac{N}{A} + \frac{N \cdot \rho_P (y - x \cdot \tan \alpha) \cos \theta}{J - I_y \cdot \tan \alpha}$$

$$= \frac{N}{A} + \frac{N \cdot \rho_P (y - x \cdot \tan \alpha) \sin \theta}{I_x - J \cdot \tan \alpha}$$

$$= \frac{N}{A} + \frac{N \cdot \rho_P (y - x \cdot \tan \alpha) \sin \theta}{I_x - J \cdot \tan \alpha}$$

$$= \frac{N}{A} + \frac{N \cdot (y_P I_y - x_P J) y + N (x_P I_x - y_P J) x}{I_x I_y - J^2}$$

$$= \frac{N}{A} + N \cdot \rho_P \times$$

$$\left[\frac{(Iy\sin\theta-J\cdot\cos\theta)\;y+(Ix\cos\theta-J\sin\theta)\;x}{I_xI_y-J^2}\right]\cdot$$

In the above equations $\frac{N}{A}$ is the portion of S which is direct stress, and the other term is the portion due to the bending moment, $M = N \cdot \rho_P$. If s represent the section modulus

$$\left(\frac{I_xI_y - J^2}{(I_y\sin\theta - J\cdot\cos\theta)\ y + (I_x\cos\theta - J\cdot\sin\theta)\ x}\right),$$
then

$$S = \frac{N}{A} + \frac{M}{s}.$$

Note. — The values of the section modulus given in the handbooks are computed from the formula $s = \frac{I}{u}$, which is the value of

HEAT ENG.

ELEC.

TAB

s for J=0 and for P located on Y-Y. For angles and Z-bars J does not equal zero.

In the above equations,

$$\begin{split} \tan\alpha &= \frac{I_x - J \cdot \tan\theta}{J - I_y \cdot \tan\theta} \\ &= \frac{I_x \cot\theta - J}{J \cot\theta - I_y} \\ &= \frac{I_x \cos\theta - J \cdot \sin\theta}{J \cos\theta - I_y \sin\theta} \end{split}$$

For any bar having a section which is symmetrical about either axis, J=0, and the values of S become

$$S = \frac{N}{A} + N \cdot \rho_P \left(\frac{I_{y} \sin \theta \cdot y + I_{x} \cos \theta \cdot x}{I_{x} I_{y}} \right) \cdot$$

If for a symmetrical section, P is on Y-Y, then $\sin \theta = 1$ and $\cos \theta = 0$, or

$$S = \frac{N}{A} + \frac{N \cdot \rho_P \cdot y}{I_x}$$

$$= \frac{N}{A} + \frac{M \cdot y}{I_x}.$$

Fig. 44

For a rectangular section, for which N is applied on Y-Y and p distant from the axis of the bar, the extreme fiber stresses are

$$S = \frac{N}{A} \left(1 \pm 6 \, \frac{p}{d} \right) \cdot$$

The equation of the neutral axis for an eccentric load is

$$y\!=\!\!\left(\!\frac{x_{P}\!\cdot\!I_{x}\!-\!y_{P}\!\cdot\!J}{x_{P}\!\cdot\!J\!-\!y_{P}\!\cdot\!I_{y}}\right)x\!+\!\frac{IxI_{y}\!-\!J^{2}}{A\left(x_{P}\!\cdot\!J\!-\!y_{P}\!\cdot\!I_{y}\right)}\cdot$$

KERNEL OR CORE-SECTION.

The kernel of a section (sometimes called the core-section) is the area within which P, the point of application of the resultant of the forces, must fall in order that the stress shall be of the same sign throughout the section. It is the area bounded by the locus of the P's corresponding to a series of neutral axes touching the periphery of the section but never crossing the section. For every side of the section there will be an apex of the kernel. If x_a , y_a and x_b , y_b are the coördinates of a and b, which are two consecutive vertices of the section, then the coördinates, x_{ab} , y_{ab} , of the vertex of the kernel corresponding to the side, ab, of the section will be

$$x_{ab} = -\frac{(x_a - x_b) J - (y_a - y_b) I_y}{A (x_a y_b - x_b y_a)},$$

$$y_{ab} = -\frac{(x_a - x_b) I_x - (y_a - y_b) J}{A (x_a y_b - x_b y_a)}$$

If ab is parallel to X-X, then

$$x_{ab} = -\frac{J}{A \cdot y_a}, \qquad y_{ab} = -\frac{I_x}{A \cdot y_a}.$$

If ab is parallel to Y-Y, then

$$x_{ab} = -\frac{I_y}{A \cdot x_a}, \qquad y_{ab} = -\frac{J}{A \cdot x_a}$$

DRAULICS

HEAT ENG.

ELEC.

TAB

The radii vectores of the kernel are lengths which for any θ need only be multiplied by the area of the section (A) to give the section modulus

$$\left(\frac{IxIy-J^2}{(I_y\sin\theta-J\cdot\cos\theta)\ y+(I_y\cdot\cos\theta-J\cdot\sin\theta)\ x}\right),$$

but these lengths must be considered positive if measured on the opposite side of G from P.

SECTION MODULUS POLYGONS.

In the equation $S = \frac{N}{A} + \frac{M}{s}$ (see Eccentric Loads), s is the section modulus. The section modulus polygon is the polygon the lengths of whose radii vectores are the graphical representations of the values of s for extreme fibers for successive values of θ from 0 to 360 degrees. The section modulus polygon is a figure whose sides are parallel to the sides of the kernel of the given section but which lie on opposite sides of the center of gravity from the sides of the kernel.

The most general value of s is

$$\frac{IxIy - J^2}{(I_y \sin \theta - J \cos \theta) \ y + (I_y \cos \theta - J \cdot \sin \theta) \ x}$$

For any section which is symmetrical about either axis, s becomes

$$s = \frac{I_x I_y}{I_y \sin \theta \cdot y + I_x \cos \theta \cdot x}$$

For any symmetrical section for which P lies on Y-Y, $\theta=90^{\circ}$, hence

$$s = \frac{I_x}{v}$$
.

If for any symmetrical section P lies on X-X, $\theta=0^{\circ}$, hence

$$s = \frac{Iy}{x}$$
.

There will be one vertex of the s-polygon for each side of the polygon bounding the section. If x_a , y_a and x_b , y_b are the coördinates of a and b, two consecutive vertices of the bounding polygon of the section, then the coördinates of the vertex of the s-polygon corresponding to the side ab of the bounding polygon will be

$$\begin{split} x_{ab} &= \frac{(x_a - x_b) \ J - (y_a - y_b) \ I_y}{x_a y_b - x_b y_a}, \\ y_{ab} &= \frac{(x_a - x_b) \ I_x - (y_a - y_b) \ J}{x_a y_b - x_b y_a}. \end{split}$$

If ab is parallel to X-X,

$$x_{ab} = rac{J}{y_a}$$
, $y_{ab} = rac{I_x}{y_a}$.

If ab is parallel to Y-Y,

$$x_{ab} = \frac{I_y}{x_a}, \qquad y_{ab} = \frac{J}{x_a}.$$

For sections symmetrical about either

X-X, or Y-Y, J=0, and the values of $\frac{I_x}{y_a}$ and $\frac{I_y}{x_a}$ can be found in the handbooks issued by the steel companies, under the column marked "Section Modulus." The vertices can then be plotted and connected by straight lines to form the s-polygon. From this s-polygon the values of s for any value of θ can be obtained graphically.

The most advantageous plane of loading for any section will be that having the greatest value of s. HY-DRAULICS

I

TAB.

DIAGONAL STRESSES.

F =axial load.

A = area of section normal to axis of bar. n-n = any diagonal section.

 θ = angle which n-n makes with axis.

S = unit axial stress.

 S_8 = unit shear along plane normal to axis.

 S_n = unit tension or compression normal to section n-n.

 S_{sn} = unit shear along section n-n.

For combined direct stress and vertical shear,

$$S_n = \frac{S}{2} \left(1 - \cos 2 \theta \right) + S_s \cdot \sin 2 \theta.$$

$$S_{sn} = \frac{S}{2} \cdot \sin 2\theta + S_s \cdot \cos 2\theta.$$

The maximum or minimum value of S_n occurs when $\cot 2 \theta = -\frac{S}{2 S_s}$, and is

max.
$$S_n = \frac{1}{2} S \pm \left(S_s^2 + \frac{S^2}{4}\right)^{\frac{1}{2}}$$
.

The maximum value of S_{sn} occurs when $\tan 2\theta = +\frac{S}{2S_s}$, and is

max.
$$S_{sn} = \left(S_s^2 + \frac{S^2}{4}\right)^{\frac{1}{2}}$$
.

For axial load only, $S_8 = 0$, hence

$$S_n = \frac{S}{2} (1 - \cos 2 \theta) = S \cdot \sin^2 \theta = \frac{F}{A} \cdot \sin^2 \theta.$$

$$S_{en} = \frac{S}{2} \cdot \sin 2 \theta = \frac{F}{2 A} \sin 2 \theta.$$

The maximum value of S_n occurs when $\theta = 90^{\circ}$, and is then the unit axial stress.

The maximum value of S_{sn} occurs when

$$\theta = 45^{\circ}$$
, and is $\frac{S}{2}$ or $\frac{F}{2A}$.

THIN PIPES, CYLINDERS, AND SPHERES.

S = unit stress in metal.

t =thickness of metal.

d = diameter.

p = unit pressure of liquid or gas.

 θ = angle which the direction of p makes with X-X.

Fig. 46.

For the transverse stress across a longitudinal section of a pipe or cylinder,

$$R_1 = R_2 = \frac{1}{2} \sum p \cdot \cos \theta = \frac{1}{2} p \cdot d.$$
$$S = \frac{R_1}{t} = \frac{p \cdot d}{2 t}.$$

For the longitudinal stress across a transverse section of a pipe, or for the stress in a thin hollow sphere,

$$S = \frac{p \cdot \frac{1}{4} \pi d^2}{\pi d \cdot t} = \frac{p \cdot d}{4 t},$$

which is one-half of the unit transverse stress in a pipe having the same diameter and thickness. HEAT

ELEC.

TAB.

RIVETED JOINTS.

Fig. 47.

a = distance center to center of two consecutive rivets in one row.

d = diameter of rivet or rivet hole.

F =stress in unriveted plate in length a.

t=thickness of plate.

 $S_t = \text{unit tensile stress.}$

 $S_c = \text{unit compressive or bearing stress.}$

 $S_s = \text{unit shearing stress.}$

 e_t = efficiency of joint for tension.

 e_c = efficiency of joint for compression.

 $e_s = \text{efficiency of joint for shear.}$

m=number of shearing sections of rivets in distance a. (Notice that for butt joints each rivet has two shearing areas.)

n = number of bearing areas of rivets in distance a.

$$\begin{split} F &= t \; (a-d) \; S_t = m \cdot \frac{1}{4} \, \pi d^2 \cdot S_s = n \cdot t \cdot d \cdot S_c. \\ e_t &= \frac{a-d}{a} \cdot \\ e_s &= \frac{m \cdot \pi \cdot d^2 S_s}{4 \cdot a t S_t} \cdot \\ e_c &= \frac{n \cdot d S_c}{a S_t} \cdot \end{split}$$

For maximum efficiency, make $e_t = e_s = e_c$, for which

$$d = \frac{4 \cdot n \cdot S_c \cdot t}{m \cdot \pi \cdot S_s},$$

and

$$a = \frac{4 \, n S_c t}{m \pi S_s} \left(1 + n \, \frac{S_c}{S_t} \right).$$

The allowable value of S_c is usually 2 S_s .

For single riveted lap joints the maximum efficiency is approximately 55 per cent, for double riveted lap joints approximately 70 per cent, for triple riveted lap joints approximately 75 per cent, and for triple and double riveted butt joints approximately 80 per cent.

BEAMS.

Vertical Shear. The vertical shear at any section of a horizontal beam is equal to the sum of the vertical components of the reactions to the left of the section minus the sum of the vertical components of the loads to the left of the section.

For any beam the vertical shear upon the right side of the left support of any span is

$$V_1 = \frac{M_2 - M_1}{l} + \frac{1}{2} wl + \Sigma F \left(1 - \frac{a}{l}\right),$$

where

 M_1 = the moment at the left support,

 M_2 = the moment at the right support, w= the uniform load per lineal unit,

F =any concentrated load.

a =the distance from the left support to F_{ϵ}

l = the length of span.

HY-DRAULICS

HEAT ENG.

ELEC.

LEB

Shearing Stresses. If V = vertical shear at any section,

$$S_8 = \frac{V}{A},$$

where S_s is the average unit shear.

The actual unit vertical shear at any point is equal to the unit horizontal shear at that point, and may be determined by the following equation:

$$S_{s} = \frac{V}{I \cdot b} \cdot \sum_{y}^{c} (y \cdot dA), *$$

where b is the breadth of the section at the given point, y is the distance of the point considered from the neutral axis, and c is the distance from the neutral axis to the extreme fiber on the same side as the point considered.

The maximum value of S_s occurs at the neutral axis, and is

max.
$$S_8 = \frac{V}{I \cdot b} \int_0^c y \cdot dA = \frac{V}{I \cdot b} \cdot A_1 y_1$$
,

where A_1 is the area of the portion of the section on one side of the neutral axis, and y_1 is the distance from the neutral axis to the center of gravity of the portion of the section on one side of the neutral axis.

For a rectangular section, the maximum unit shear is $\frac{3}{2}$ of the mean unit shear.

For Diagonal Shear, see Diagonal Stresses, page 62.

Bending Moment. The bending moment at any point for any beam is

$$M = M_1 + V_1 x - \frac{1}{2} wx^2 - \Sigma F(x - a)$$

^{*} See "Merriman's Mechanics of Materials," page 269.

 M_1 = bending moment at the left support, V_1 = vertical shear upon the right side of the left support,

F = any concentrated load upon the left of the section considered,

x =distance from the left support to the section considered.

For any beam of one span V_1 is equal to the vertical component of the left reaction.

The maximum positive moments occur at those sections for which $\frac{dM}{dx}$ becomes equal to or passes through zero, that is where the shear becomes or passes through zero. The negative moments at the supports may have the largest numerical values, and for these points $\frac{dM}{dx}$ does not equal zero, since the tangents to the moment curve are not horizontal at these points.

Theorem of Three Moments. For any two consecutive spans of a continuous beam, let

 M_1 = moment at the left support,

 M_2 = moment at the middle support,

 M_3 =moment at the right support,

 l_1 =length of the first span,

 l_2 = length of the second span,

l = length of span for equal spans,

 w_1 =uniform load per lineal unit on first span,

 w_2 = uniform load per lineal unit on second span,

 F_1 = any concentrated load on the first span,

 F_2 = any concentrated load on the second span,

 a_1 = distance from first support to F_1 ,

 a_2 = distance from middle support to F_2 .

HY-DRAULIOS

H

AB. EB. Then, for uniform loads only,

$$M_1l_1+2 M_2 (l_1+l_2)+M_3l_2=-\frac{1}{4} w_1l_1^3-\frac{1}{4} w_2l_2^3.$$

For equal spans with equal uniform loads,

$$M_1+4 M_2+M_3=-\frac{1}{2} w l^2$$
.

For concentrated loads only,

$$\begin{split} &M_1 l_1 + 2 \ M_2 \ (l_1 + l_2) + M_3 l_2 \\ &= -F_1 \left(a_1 l_1 - \frac{a_1^3}{l_1} \right) - F_2 \left(2 \ a_2 l_2 - 3 \ a_2^2 + \frac{a_2^3}{l_2} \right) \cdot \end{split}$$

Flexural Stresses. The tensile and compressive stresses in a beam, produced by bending, can be determined by placing $\frac{N}{A} = 0$ in the formula for S given under Eccentric Loads, which gives

$$S = \frac{M}{s}$$
.

For combined flexure and direct stress, the tensile and compressive stresses can be computed for prisms by the formulæ given under *Eccentric Loads*, and for long members by the formulæ given for *Eccentrically Loaded Columns*.

Elastic Curves. The curve which is assumed by the neutral surface of a beam under load is called the elastic curve.

The radius of curvature of the elastic curve is

$$R = \frac{EI}{M} = \frac{dl^3}{dx \cdot d^2y} = \frac{dx^2}{d^2y},$$

from which the equation of the elastic curve can be obtained, for any particular case, by placing M equal to $EI\frac{d^2y}{dx^2}$, and by making two integrations to obtain an equation in terms of x and y.

The deflection of a beam at any given point is obtained by substituting the particular value of x in the equation of the elastic curve and solving for y. The maximum deflection occurs at the section for which

$$\frac{dy}{dx} = 0.$$

(For particular cases, see Table of Beams.)

TABLE OF BEAMS.

Note. — The equations for elastic curves and the values of Δ apply only to beams of uniform section.

Beams Supported at Both Ends and Uniformly Loaded.

$$\begin{split} R_1 &= R_2 \\ &= \frac{1}{2} \, w l = \frac{W}{2} \cdot \\ V &= R_1 - w x \cdot \\ M &= R_1 x - \frac{1}{2} \, w x^2 \\ &= \frac{1}{2} \, w l x - \frac{1}{2} \, w x^2 \\ &= \frac{1}{2} \, W x - \frac{1}{2} \, w x^2 \cdot \\ \end{split}$$

$$M_m = \frac{1}{8} w l^2 = \frac{1}{8} W l.$$

$$EI \frac{d^2y}{dx^2} = \frac{1}{2} w l x - \frac{1}{2} w x^2.$$

$$24 EIy = w \left(-x^4 + 2 l x^3 - l^3 x \right).$$

$$y = \Delta$$
 when $x = \frac{l}{2}$.

$$\Delta = \frac{5}{384} \frac{wl^4}{EI} = \frac{5}{384} \frac{Wl^3}{EI}.$$

$$x = \sqrt{\frac{2al - a^2}{3}},$$

$$\Delta = \frac{F}{3EI} \left(\frac{2al - a^2}{3}\right)^{\frac{3}{2}} \left(1 - \frac{a}{l}\right).$$

Beam Supported at Both Ends and Loaded with Several Concentrated Loads.

$$R_1 = \frac{\sum F(l-a)}{l}.$$

$$R_2 = \frac{\sum Fa}{l} = \sum F - R_1.$$

$$V = R_1 - \sum_{0}^{x} F.$$

$$M = R_1 x - \sum_{0}^{x} F(x-a).$$

The maximum moment (M_m) occurs at the section for which $R_1 - \sum_{0}^{x} F$ equals or passes through zero.

For a system of movable loads the maximum moment will occur under one of the loads, the loads being in such a position that the center of the span is midway between the center of gravity of all the loads and the section at which the maximum moment occurs.

The maximum deflection of a beam loaded with several loads is the sum of the deflections produced by each load at the section

HY-DRAULICS

HEAT

ELEC. ENG. at which the maximum deflection for the entire system of loads occurs. The deflections produced by each load can be obtained

Fig. 51.

by means of the equation of the elastic curve for a single load.

Cantilever Beam with Uniform Load.

 $24 EIy = wx^4 - 4 wlx^3 + 6 wl^2x^2$.

$$\Delta = \frac{1}{8} \frac{wl^4}{EI} = \frac{1}{8} \frac{Wl^3}{EI}.$$

tions, thus obtained for the moments at the supports. Then

$$egin{aligned} V_1 &= rac{M_2}{l_1} + rac{1}{2} \, w_1 l_1. \ V_{2a} &= W_1 - V_1. \ V_{2b} &= rac{M_3 - M_2}{l_2} + rac{1}{2} \, w_2 l_2. \ V_{3a} &= W_2 - V_{2b}, ext{ etc.} \end{aligned}$$

For equal spans with equal uniform load over the entire beam, the ends of the beam resting upon supports, the moment at any support is Kwl^2 or KWl, and the vertical shear is Nwl or NW, where K and N have the values given in the following table. For many practical calculations the moment at a support one span from the end is assumed to be $-\frac{1}{10}Wl$, and for intermediate supports $-\frac{1}{12}Wl$.

For a continuous beam with fixed ends consider an imaginary span to be added at each end of the beam, with the free ends resting upon supports. Then write the equation of three moments for each two consecutive spans, making l=0 for the first and last spans, and compute the moments at the supports as shown above.

Continuous Beam with Concentrated Loads.

Determine the moments at the supports in a similar manner to that employed for continuous beam with uniform load, employing the equation of three moments for concentrated loads.

HY-DRAULICS HEAT ENG.

ELEC. ENG.

STRUTS AND COLUMNS.

Euler's Formula.

$$EI\frac{d^{2}y}{dx^{2}} = -Fy.$$

$$dx = \left(\sqrt{\frac{EI}{F}}\right)\left(\frac{dy}{\sqrt{a^{2} - y^{2}}}\right).$$

$$x = \sqrt{\frac{EI}{F}} \cdot \sin^{-1}\left(\frac{y}{a}\right), \text{ or }$$

$$y = a \cdot \sin\left(x\sqrt{\frac{F}{EI}}\right).$$

Since y = a when $x = \frac{l}{2}$, $\frac{l}{2} \sqrt{\frac{F}{EI}}$ must equal

 $\frac{\pi}{2}$, or $F = EI \frac{\pi^2}{l^2}$.

$$\frac{F}{A} = \pi^2 E \left(\frac{r}{l}\right)^2$$
, for round ends.

For one end round and the other end fixed, replace l by $\frac{4}{3}l$ and π by 2π , which gives

$$F = \frac{9}{4}EI\frac{\pi^2}{l^2}.$$

$$\frac{F}{A} = \frac{9}{4}\pi^2E\left(\frac{r}{l}\right)^2.$$

For both ends fixed, replace l by $\frac{3}{2}l$ and π by 3π , in the formula for round ends, which gives

$$F = 4 EI \frac{\pi^2}{l^2} \cdot \frac{F}{A} = 4 \pi^2 E \left(\frac{r}{l}\right)^2 \cdot \frac{\Gamma}{A}$$

Rankine's Formula. (Sometimes called Gordon's Formula.)

From the formula for eccentric loads for a symmetrical section (page 57), the maximum stress will be

$$S = \frac{F}{A} + \frac{My}{I}$$

where y is the distance from the neutral axis to the extreme fiber.

But, $I = Ar^2$, M = Fa and $a = K\frac{l^2}{y}$, where K is some constant depending upon character and condition of the column. Hence

$$S = \frac{F}{A} \left[1 + K \left(\frac{l}{r} \right)^2 \right], \text{ or }$$

$$\frac{F}{A} = \frac{S}{1 + K \left(\frac{l}{r} \right)^2}.$$

The following values of K are recommended in the Civil Engineers' Pocket Book:*

Material.	Both Ends Fixed.	One End Fixed, One End Round.	Both Ends Round.
Timber Cast Iron Wrought Iron . Steel	1/3000	1.95/3000	3/3000
	1/5000	1.95/5000	4/5000
	1/36000	1.95/36000	4/36000
	1/25000	1.95/25000	4/25000

Ritter's Formula. Ritter's formula is the same as Rankine's formula except that the

^{*} American Civil Engineers' Pocket Book, p. 307.

expression $\frac{S_e}{nE}$ is used for K, in which S_e is the elastic limit of the material, and n is equal to π^2 for round ends, $\frac{9}{4}$ π^2 for one end round and one end fixed, and 4 π^2 for both ends fixed.

The Straight Line Formula. The straight line formula is

 $\frac{F}{A} = S - C \frac{l}{r}$

where C is a constant depending upon the character and condition of the column.

Merriman gives the value of C in the above equation to be

 $C = \frac{2}{3}S\left(\frac{S}{3nE}\right)^{\frac{1}{2}}$,

which is obtained by making the straight line a tangent to the curve for Euler's formula passing through the point S for $\frac{l}{r} = 0$, the values of n being those given for Ritter's formula.

Values of constants for the straight line formula, as determined by T. H. Johnson, for rupture, are given in the Civil Engineers' Pocket Book * as follows:

Kind of Column.	s.	C.	$_{l/r.}^{\rm Limit}$

For east iron columns, for which $\frac{l}{r}$ does not exceed 70, the Chicago ordinance allows

$$10,000-60 \frac{l}{r}$$
.

For timber columns, the formula is changed to

$$\frac{F}{A} = S\left(1 - C\frac{l}{d}\right),$$

^{*} Main members and laterals, respectively.

[†] Impact of live loads to be taken into account by adding I=S $\frac{300}{L+300}$, in which S= actual live load, and L= length of bridge loaded.

ELEC.

in which S is the allowable compressive stress along the grain, and d is the diameter. The Chicago ordinance (Mr. Benj. E. Winslow's formula) uses $\frac{1}{80}$ for C, for values of $\frac{l}{d}$ not greater than 30. Ketchum's Specifications for Steel Frame Buildings gives $C = \frac{1}{100}$.

Eccentrically Loaded Columns. By adding the bending stress $\frac{My}{I}$ to Rankine's formula, replacing M by Fe, and I by Ar^2 , the formula becomes

$$S = \frac{F}{A} \left[1 + K \frac{l^2}{r^2} + \frac{ey}{r^2} \right],$$

in which the constants are those given for Rankine's formula, e is the eccentricity, and y is the distance from the neutral axis to the extreme fiber.

A more general formula for combining direct and bending stresses is

$$S = \frac{F}{A} \pm \frac{My}{I \mp \frac{\alpha F l^2}{\beta E}}, *$$

in which M is the apparent bending moment, y is the distance to the extreme fiber, I is the moment of inertia, E is the modulus of elasticity, and α and β are constants, β/α being 9.6 for a simple beam uniformly loaded and 12 for a simple beam with a load at the center.

The following formula for steel struts, given in Ketchum's Specifications for Steel Frame Buildings, is a special case of the last formula.

$$S = \frac{F}{A} + \frac{My}{I - \frac{Fl^2}{10 E}}$$

^{*} See "Apparent Combined Stresses," Merriman's "Mechanics of Materials."

Circular Sections. .

Twisting moment, M = Fa.

Circular Sections

dA

Fig. 61.

Resisting moment, $M_r = \int \frac{\rho^2}{R} S dA$, where S is the shearing stress at the extreme fiber.

$$M = M_r$$
, or

 $M=\frac{SI_0}{R},$

where I_0 is the polar moment of inertia.

For a solid round shaft $\frac{I_0}{R} = \frac{1}{2} \pi R^3$, hence

$$M = \frac{1}{2} \pi R^3 S$$
, or $S = \frac{2M}{\pi R^3}$.

Non-Circular Sections. (Taken from Merriman's "Mechanics of Materials.") For non-circular sections the above formulæ are only approximate.

For an *elliptical section* whose major axis is m and whose minor axis is n the maximum stress is

$$S = \frac{16 Fa}{\pi m n^2}, \quad \text{or} \quad$$

$$M = \frac{\pi m n^2 S}{16}.$$

For a rectangular section whose long side is m and whose short side is n, the maximum stress is

$$S = rac{9}{2} rac{Fa}{mn^2}$$
, or $M = rac{2}{9} mn^2 S$.

Transmission of Power. The horse-power which is transmitted by a shaft is

$$H.P. = \frac{2 \pi a \cdot F \cdot \omega}{550 \times 12},$$

where a = moment arm in inches, $\omega = \text{number of revolutions per sec.}$

But
$$Fa = \frac{SI_0}{R}$$
, hence
$$\text{H.P.} = \frac{2 \pi \omega SI_0}{550 \times 12 R} = 0.000952 \frac{\omega SI_0}{R}.$$

ELLIPSOID OF STRESS.

For any point within a stressed body, the resultant unit stress upon any plane is proportional to the radius vector of an ellipsoid. The principal axes of the ellipsoid coincide with the principal stresses, which stresses are normal to the planes upon which they act. For a plane not normal to a principal axis the resultant stress is not normal to the plane.

REINFORCED CONCRETE.

Notation.

Let A = area, b = width of beam, b' = width of stem, d = depth to center of steel, E = modulus of elasticity, f = unit stress, M = moment, $n = E_s \div E_c$, P = total load, p = ratio of area of longitudinal steel to area of section of member,

q=ratio of volume of circumferential steel to volume of column, s=spacing, subscript (c) refers to concrete, subscript (s) refers to steel, t=thickness of flange, u=unit bond stress, V=total shear, v=unit shearing stress, $\Sigma_0=$ sum of perimeters of bars, and other values are as indicated in the figures or as specifically stated.

Columns.

For columns with longitudinal steel only.

$$P = f_c A [1 + (n-1) p].$$

 $f_s = n f_c.$

For columns with spiral and longitudinal steel. the proper form of equation is not well estab-The ultimate unit load may be expected to be

$$\frac{P}{A} = f_c (1-p) + f_5 p + K f_8' q,$$

in which f_8 is the yield point of longitudinal steel, f,' is the yield point of the circumferential steel, and K is a factor the value of which will usually be between 1.0 and 1.5

Beams.

For beams, in general,

$$f_s = M \div (A_s j d).$$

$$f_c = \frac{f_s k}{n (1 - k)}.$$

$$jd = d - z.$$

$$v = V \div (b'jd).$$

$$u = V \div (j d\Sigma_0).$$

Per vertical stirrup,

P = Vs/id. Per stirrup at 45°.

r stirrup at
$$45^{\circ}$$
,
 $P=0.7Vs/id$.

For rectangular beams,

$$p = 1 \div \left[2 \frac{f_s}{f_c} \left(\frac{f_s}{nf_c} + 1 \right) \right] \cdot \\ k = \sqrt{2 p n + (p n)^2} - p n. \\ z = kd \div 3. \\ f_c = 2 M/jkbd^2 = 2 p f_s/k.$$
(For $f_s = 16,000$ and $f_c = 650$, $p = 0.0077$.)
(j is approximately $\frac{7}{8}$.)

For T-beams,

$$kd = \frac{2 n dA_s + bt^2}{2 nA_s + 2 bt}$$

$$z = \frac{(3 kd - 2 t) t}{(2 kd - t)^3}$$

(For thin flanges z is often assumed $\frac{t}{2}$.)

For beams reinforced for compression,

$$k = \left[2 n \left(p + p' \frac{d'}{d}\right) + n^2 (p + p')^2\right]^{\frac{1}{2}} - n (p + p').$$

$$z = \frac{\frac{1}{3} k^3 d + 2 p' n d' \left(k - \frac{d'}{d}\right)}{k^2 + 2 p' n \left(k - \frac{d'}{d}\right)}.$$

For p'=0.5 p, $d' \div d=0.10$, and n=15; p=0.0135 to make f_s 16,000 when f_c is 747, for which $M=185 bd^2$; p=0.010 to make f_s 16,000 when f_c is 650, for which $M=140 bd^2$.

For p' = 0.5 p, $d' \div d = 0.15$, and n = 15;

p = 0.013 to make f_s 16,000 when f_c is 747, for which M = 175 bd^2 ; p = 0.0094 to make f_s 16,000 when f_c is 650, for which M = 130 bd^2 .

For p' = p, $d' \div d = 0.10$, and n = 15;

p = 0.0195 to make f_s 16,000 when f_c is 747, for which $M = 275 \ bd^2$; p = 0.014 to make f_s 16,000 when f_c is 650, for which $M = 200 \ bd^2$.

For p' = p, $d' \div d = 0.15$, and n = 15;

p = 0.018 to make f_s 16,000 when f_c is 747, for which $M = 250 \ bd^2$; p = 0.0125 to make f_s 16,000 when f_c is 650, for which $M = 175 \ bd^2$.

Flat Slab Floors.

For flat slab floors extending over several panels in each direction, the following requirements are in accordance with the recommendations * of the Joint Committee on Concrete and Reinforced Concrete.

Column Capitals. The minimum edge thickness should be 1½ inches. The slope of the conical surface should not be more than 45 degrees with the vertical. The minimum diameter (or dimension parallel to edge of panel) should be not less than one-fifth of the panel distance (measured center to center of adjacent columns), and it is desirable to use 0.225 times the panel distance.

Dropped Panels. The minimum width should be four-tenths of the panel distance, and the maximum offset should be five-tenths

^{*} For the Final Report of the Joint Committee on Concrete and Reinforced Concrete see Proceedings of the American Society for Testing Materials, vol. XVII, 1917, pp. 202–262.

of the thickness of the slab outside of the dropped panel.

Slab Thickness. For, t= the total thickness of slab in inches, L= panel distance in feet, and w= the total dead and live load in pounds per square foot; minimum values of t should be $0.024 L \sqrt{w} + 1\frac{1}{2}$ for slabs without dropped panels, $0.020 L \sqrt{w} + 1$ for slabs with dropped panels, and $0.03 L \sqrt{w} + 1\frac{1}{2}$ for the dropped panels themselves. Also, t should not be less than six inches, nor less than one-thirty-second of the panel distance for floors, nor less than one-fortieth of the panel distance for roofs.

Bending Moments in Girdless Slabs. For c = diameter of capital in feet, and panel dis-

Fig. 64.

tances in feet and in accordance with Fig. 64, and for other values as already given, interior panels may be designed upon the assumption that the sum of the positive bending moments for one inner and two outer sections on one line of length L_1 is $\frac{1}{25}$ w L_1 ($L_2 - \frac{2}{3}$ c)² foot-pounds,

of which at least 25 per cent should be resisted by the inner section, while the two outer sections should resist at least 55 per cent of the positive moment in slabs without dropped panels, and at least 60 per cent in slabs with dropped panels. Also, for the slab thickness away from the dropped panels, at least 70 per cent of the positive moment should be resisted by the two outer sections.

For interior panels, assume the sum of the negative moments to be resisted by one mid-

Wall Panels. At the first row of columns away from the wall and also at the sections halfway from this row of columns to the wall, increase the moments by 20 per cent of the values as determined for interior panels. wall girders or cantilever restraint does not exist at the wall, increase the moments of the outer section and the column head section by 20 per cent of the values as determined for interior panels, for designing reinforcement parallel to the wall.

Shear and Diagonal Tension. As a measure of diagonal tension assume $v = \frac{wL}{24 id}$ for slabs

without dropped panels, and $v = \frac{wL}{20 id}$ for slabs with dropped panels. For punching shear at peripheries of capitals and dropped panels, assume a total shear 25 per cent greater than the actual punching shear, computed on the basis of a load which is uniformly distributed.

Bending Moments in Columns should be given special consideration.

STATIC PRESSURE.

p=wh, in which for water at ordinary temperatures w is 62.4 lb. per cu. ft. The density of water for particular temperatures is shown in Fig. 65.

Fig. 65.

Fig. 66.

For h in feet,

or

p=62.4 h lb. per sq. ft.

=0.433 h lb. per sq. in.

h=2.306 p, for p in lb. per sq. in.

P = pA

= $\int wh dA$, for any surface,

=whA, for a horizontal surface,

or

 $=\frac{1}{2} whA$, for a rectangular surface with one edge at the surface of the water h being measured to the lower edge.

If p is the average unit pressure,

$$P_v = P \cos \theta = pA_h.$$

$$P_h = P \sin \theta = pA_w.$$

CENTER OF PRESSURE.

$$y_p = I_0 \div M_0$$

$$= Ar_0^2 \div Ay_c$$

$$= y_c + \frac{r_{cg^2}}{y_c},$$

in which r is the radius of gyration.

Fig. 67.

WEIRS.

q = cu. ft. per sec. h =observed head in v = velocity ofproach. Velocity head,

$$h_v = \frac{v^2}{2\,g} \cdot$$

Rectangular Weirs.

Francis' formula is

$$q = 3.33 [L - 0.1 nh] [(h + h_v)^{\frac{3}{2}} - h_v^{\frac{3}{2}}],$$

in which n is the number of end contractions.

Fteley and Stearns' formula for suppressed weirs is

$$q = 3.31 L (h + 1.5 h_v)^{\frac{3}{2}} + 0.007 L.$$

Bazin's formula for suppressed weirs is q =

$$\left(0.405 + \frac{0.00984}{h}\right) \left[1 + 0.55 \left(\frac{h}{H+h}\right)^{2}\right] L \sqrt{2g} \cdot h^{\frac{3}{2}}.$$

A general equation for discharge is

$$q = c \frac{2}{3} \sqrt{2g} \cdot L (h + nh_v)^{\frac{3}{2}},$$

for which Hamilton Smith's values of n are 1.4 for contracted weirs and $1\frac{1}{3}$ for suppressed weirs.

Smith's values of c for contracted weirs are plotted in Fig. 69 and for suppressed weirs in Fig. 70.

Contracted Weirs. No End Contraction.

Fig. 71. Cippoletti Weir.

Trapezoidal Weirs.

Cippoletti's formula is $q = 3.367 Lh^{\frac{3}{2}}$.

Triangular Weirs.

 $q = c \cdot \frac{8}{15} \tan \theta \sqrt{2g} \cdot h^{\frac{5}{2}}$.

Triangular Weir.

For $\theta = 45^{\circ}$, and for an average value of c, $q=2.6\,h^{\frac{5}{2}}$

Submerged Weirs.

The formula for submerged weirs given in the American Civil Engineers' Pocket Book * is

^{*} American Civil Engineers' Pocket Book, page 854.

$$q = cL\sqrt{2gh} \cdot \left\lceil h - \frac{1}{3} (h - h') \right\rceil,$$

in which c is from 0.58 to 0.63 for a sharp crest.

Fig: 73.

Submerged Weir.

Herschel's formula* is

$$q=3.33 L(nh)^{\frac{3}{2}}$$

in which n has values indicated in Fig. 74.

ORIFICES AND JETS.

Discharge.

$$V = \sqrt{2gh}$$
 or $h = \frac{V^2}{2g}$.

Fig. 75. Standard Orifice.

Fig. 76. Standard Tube.

For a standard orifice,

v = from 0.97 V to 0.99 V.A' = from 0.57 A to 0.62 A.

 $q = cA \sqrt{2} \frac{gh}{gh}$

in which an average value of c is 0.61.

^{*} Trans. Am. Soc. C. E., 1885, vol. XIV, p. 194.

For a standard tube,

$$v = 0.82 \ V = 0.82 \ \sqrt{2 \ gh},$$

 $q = 0.82 \ A \ \sqrt{2 \ gh}.$

An inward projecting tube may reduce the discharge to $0.5 A \sqrt{2gh}$, and a diverging or compound tube will increase the discharge.

Force and Energy.

The energy of a jet discharging W lb. of water is $W \frac{v^2}{2a}$.

The force of a jet discharging W lb. of water per second, and impinging at right angles to a fixed plate, is $W^{\frac{v}{a}}$.

The *impulse* exerted by a jet is equal to the reaction. For a jet deflected by a fixed

Fig. 77. $= 2 W \frac{v}{a} \sin \frac{\theta}{2}$

The total component of force parallel to F_1 (Fig. 77) is

$$F_1 - F_2 \cos \theta = W \frac{v}{g} (1 - \cos \theta).$$

For moving plates the force upon the plate is that which would be exerted upon a fixed plate by a jet having a velocity equal to the relative velocity of the given jet to the plate, and the work done can be computed from the forces (impulse and reaction) and the velocity of the plate. The velocity of the plate determines the distance through which the force acts.

Also, the energy given up by the jet may be computed by the formula $\frac{W}{2g}(v_1^2-v_2^2)$, in which v_1 is the absolute velocity with which the jet strikes the plate and v_2 is the absolute velocity of the jet leaving the plate.

FLOW IN PIPES. Long Pipes.

Fanning's formula is

$$h_f = 4f \frac{L}{D} \frac{v^2}{2g}$$
, or $v = \sqrt{\frac{2gDhf}{4fL}}$,

whence $q = 3.15 \left[\frac{hfD^5}{fL} \right]^{\frac{1}{2}}$ or $D = 0.632 \left[\frac{fLq^2}{h_f} \right]^{\frac{1}{6}}$.

Values of f for east iron pipe are indicated in Fig. 78.* (The formula for h_f is frequently

^{*} Plotted for average values given in American Civil Engineers' Pocket Book, pp. 845, 846,

ELEC.

used in the form $h_f = f \frac{L}{D} \frac{v^2}{2g}$, in which case the value of f is four times the value here used.)

Chezy's formula is

$$v = C\sqrt{rs}$$
.

in which r is the hydraulic radius, which is equal to D/4 for a pipe, s is the slope of the hydraulic grade line or the friction head divided by the length, and C is a coefficient, for which values for cast iron pipes are indicated in Fig. 79.

The Chezy formula is used for flow in open channels as well as for flow in pipes.

Flamant's formulæ are

 $v = 86.38 D^{\frac{5}{7}s^{\frac{4}{7}}}$ for new cast iron pipes,

 $v = 76.28 D^{\frac{5}{7}} s^{\frac{4}{7}}$ for old cast iron pipes,

in which s is the same as for the Chezy formula.

Various Losses of Head.

The loss at entrance for a pipe is

$$h_f = \left(\frac{1}{c_{v^2}} - 1\right) \frac{v^2}{2 a}$$

in which c_n is the coefficient of velocity.

For a square edge at the entrance, the loss may be taken as $0.5 \frac{v^2}{2g}$, or for an inward pro-

jecting pipe it may be considered to be $\frac{v^2}{2g}$.

The loss due to expansion at a point of sudden enlargement is

$$h_f = \frac{(v_1 - v_2)^2}{2 \ q}$$
,

in which v_1 is the velocity in the smaller section and v_2 is the velocity in the larger section.

Other losses of head occur at elbows, valves, and sudden contractions. These are ordinarily stated in the form $K\frac{v^2}{2g}$, in which K is a coeffi-

cient for the particular case. For practical problems the equivalent length of pipe may often be used.

Equivalent Pipe Length.

A convenient method of taking account of losses of head at entrance, elbows, curves, and fittings, and the head remaining as velocity head $\left(\frac{v^2}{2\,g}\right)$ is to add to the actual length of pipe a length in which the friction loss would be equivalent to the particular loss, using the total equivalent length of pipe in computing size or flow. The equivalent length of pipe required to produce any loss, $K\frac{v^2}{2\,g}$, is $\frac{K}{4\,f}$ times the diameter, in which f is the friction factor for Fanning's formula. For ordinary computations for iron pipe the following equivalent lengths may be used:

For loss at entrance, 25 diameters, For loss at an elbow, 10 diameters, For loss at end, $\left(\frac{v^2}{2g}\right)$, 50 diameters.

Bernoulli's Theorem.

Neglecting friction, $P/w+v^2/2$ g+z is a constant for all points along a given pipe, z being the elevation of the point above a given plane of reference.

FLOW IN CHANNELS.

Chezy's formula is

$$v = C\sqrt{rs}$$

in which s is the slope, r is the hydraulic radius, which is equal to the area of the cross-section of the water divided by the length of the wetted perimeter, C is a coefficient which depends upon the roughness of the channel, and v is the mean velocity.

HEAT ENG.

ELEC. ENG.

LES

Kutter's formula for the value of C for use in the Chezy formula is

$$C = \frac{\frac{1.811}{n} + 41.65 + \frac{0.00281}{s}}{1 + \frac{n}{\sqrt{r}} \left(41.65 + \frac{0.00281}{s}\right)},$$

in which r and s are the same as given for the

Kutter's Coefficient.

Chezy formula, and n is the coefficient of roughness for which some of the values are as follows:

- n = 0.010 for neat cement,
- n=0.013 for clean brick and sewers.
- n = 0.015 for unclean sewers,
 - n = 0.020 for new canals.
 - n = 0.025 for ordinary canals,
- n=0.035 for canals in bad condition.

Values of C for n=0.015 and n=0.025 are indicated in Fig. 80, for s=0.01 and for s=0.0001.

Bazin's formula for the value of C for use in the Chezy formula is

$$C = \frac{157.6}{1 + \frac{1.811 \ m}{\sqrt{r}}}$$
$$C = \frac{87}{1 + \frac{1.811 \ m}{\sqrt{r}}}$$

óŗ

$$C = \frac{87}{0.552 + \frac{m}{\sqrt{r}}}.$$

in which r is the hydraulic radius and m is a coefficient of roughness for which some of the values are:

m = 0.16 for planks or bricks, m = 1.30 for ordinary canals,

m=1.75 for canals in bad condition.

The ratio of the mean velocity in a channel to the maximum surface velocity is subject to a considerable variation, its approximate value being 0.8.

The ratio of the mean velocity for any vertical section to the velocity at the mid-depth is approximately 0.98.

For any vertical section, the velocity at 0.6 of the depth from the surface will be approximately the mean velocity for the section.

For any vertical section the mean velocity is approximately 0.9 of the surface velocity.

HYDRAULIC GRADE LINE

The hydraulic grade line is the line connecting the points to which water would rise in a piezometer tube, if the tube were applied to consecutive points throughout the length of a pipe or conduit. The distance from the pipe to the hydraulic grade line at any point is the pressure head at the given point. The slope of the hydraulic grade line is the hydraulic gradeline is the hydraulic gradeline is the hydraulic gradeline is the loss of head which exists between the two corresponding points of the conduit.

HEAT ENGINEERING.

COMPILED BY G. A. GOODENOUGH Professor of Thermodynamics, University of Illinois

ELEMENTS OF THERMODYNAMICS.

Notation.

M = weight of substance, in lb.

p = absolute pressure, in lb. per sq. ft.

t = temperature, deg. F.

T = t + 459.6 = absolute temperature.

V, v = volume, in cu. ft.

U, u = internal energy, in B.t.u.

I, i =thermal head, in B.t.u.

S, s = entropy.

Q, q = heat absorbed in B.t.u.

J = 777.6 = mechanical equivalent of heat; i.e., 777.6 ft. lb. = 1 B.t.u.

 $A = \frac{1}{J}$ = reciprocal of mechanical equiva-

 \overline{W} = external work done during a change of state.

 c_n = specific heat at constant volume.

 c_p = specific heat at constant pressure.

The small letters, v, u, i, s refer to 1 lb. of the substance, the capital letters V, U, I, S refer to M lb. Thus V = Mv, S = Ms, etc.

Fundamental Equations: Definitions.

The state of a substance initially given by p_1 , v_1 , T_1 changes to a second state given by p_2 , v_2 , T_2 . The work done by the substance in

expanding is $W_{12} = \int_{v_1}^{v_2} p \, dV$; and if Q_{12} denotes

the heat absorbed during the process, the first law is expressed by the energy equation

$$Q_{12} = U_2 - U_1 + A \int_{V_1}^{V_2} p \, dV.$$
102

103

Or in differential form,

$$dQ = du + Ap \, dV.$$

The thermal head I is defined by the equation

$$I = U + ApV,$$

whence

$$dQ = dI - AV dp.$$

For a change of state at constant pressure, $dQ = dI_{\bullet}$ or

$$Q_{12} = I_2 - I_1.$$

Similarly, for a change of state at constant volume

$$Q_{12} = U_2 - U_1.$$

The entropy S may be defined by the relation

$$dS = \frac{dQ}{T} + \frac{dH}{T},$$

where H denotes, not the heat absorbed by the substance from the surroundings, but the heat generated within the substance due to friction, wire drawing, etc. If the change of state is adiabatic (no heat absorbed or rejected), then dQ = 0 and $ds = \frac{dH}{T}$. If the change is also frictionless, dH = 0, and dS = 0, or S is constant. In many changes H is negligible, whence

$$ds = rac{dQ}{T}$$
, or $dQ = T dS$. $Q_{12} = \int_{s_1}^{s_2} T dS$.

It follows that if the change of state is represented graphically on a plane with T and S as the axes, the area between the curve and the S-axis represents the heat absorbed.

PERFECT GASES.

The characteristic equation of a perfect gas is

$$pv = BT$$
, or $pV = MBT$,

in which B is the so-called gas constant. The equation may be given the homogeneous form

$$\frac{p_1 V_1}{T_1} = \frac{p_2 V_2}{T_2} = \frac{p V}{T} = B.$$

HEAT ENG.

ELEC.

For a perfect gas

$$c_p - c_v = AB = \frac{1}{777.6} B$$

 $c_n/c_n = k.$

and

VALUES OF B, c_p , c_v , AND k FOR GASES.

For a change of a gas from an initial state p_1 , V_1 , T_1 , to a final state p_2 , V_2 , T_2 ,

$$U_2 - U_1 = Mc_v (T_2 - T_1) = \frac{A}{k-1} (p_2 V_2 - p_1 V_1),$$

$$I_2 - I_1 = Mc_v (T_2 - T_1) = \frac{Ak}{k-1} (p_2 V_2 - p_1 V_1),$$

$$S_2 - S_1 = M \left[c_p \log_e \frac{V_2}{V_1} + c_v \log_e \frac{p_2}{p_1} \right]$$

Special Changes of State.

1. Constant Volume.
$$\frac{p_2}{p_1} = \frac{T_2}{T_1}$$
. $W_{12} = 0$. $Q_{12} = U_2 - U_1 = Mc_v (t_2 - t_1)$. $S_2 - S_1 = Mc_v \log_e \frac{T_2}{T_1}$.

2. Constant Pressure.
$$\frac{V_2}{V_1} = \frac{T_2}{T_1}$$
. $W_{12} = p (V_2 - V_1) = MB (t_2 - t_1)$. $Q_{12} = Mc_p (t_2 - t_1) = \frac{Ak}{k-1} W_{12}$. $S_2 - S_1 = Mc_p \log_e \frac{T_2}{T_1}$.

3. Constant Temperature (Isothermal).

$$p_{1}V_{1} = p_{2}V_{2}. \quad W_{12} = p_{1}V_{1}\log_{e}\frac{V_{2}}{V_{1}}.$$

$$U_{2} - U_{1} = 0.$$

$$Q_{12} = AW_{12} = AMBT\log_{e}\frac{V_{2}}{V_{1}}.$$

$$S_{2} - S_{1} = \frac{Q_{12}}{T} = AMB\log_{e}\frac{V_{2}}{V_{1}}.$$
4. Adiabatic.
$$\frac{T_{2}}{T_{1}} = \left(\frac{V_{1}}{V_{2}}\right)^{k-1} = \left(\frac{p_{2}}{p_{1}}\right)^{\frac{k-1}{k}}.$$

$$W_{12} = J\left(U_{1} - U_{2}\right) = \frac{1}{k-1}\left(p_{1}V_{1} - p_{2}V_{2}\right).$$

$$Q_{12} = 0. \quad S_{2} - S_{1} = 0.$$

Also
$$W_{12} = \frac{p_1 V_1}{k-1} \left[1 - \left(\frac{p_2}{p_1} \right)^{\frac{k-1}{k}} \right]$$

5. $pv^n = const.$ The expansion and compression of gases in motors, compressors, etc., may be represented by curves having the equation $pv^n = C$, where n is a constant. The specific heat associated with such a process is $c_n = c_v \frac{n-k}{n-1}$, whence for 1 < n < k, c_n is negative.

$$\begin{split} \frac{T_2}{T_1} &= \left(\frac{V_1}{V_2}\right)^{n-1} = \left(\frac{p_2}{p_1}\right)^{\frac{n-1}{n}} \cdot \\ W_{12} &= \frac{1}{1-n} \left(p_2 V_2 - p_1 V_1\right) \\ &= \frac{p_1 V_1}{n-1} \left[1 - \left(\frac{p_2}{p_1}\right)^{\frac{n-1}{n}}\right] \cdot \\ Q_{12} &= Mc_n \left(t_2 - t_1\right). \quad S_2 - S_1 = Mc_n \log_e \frac{T_2}{T} \cdot \end{split}$$

 $AW_{12}: U_2 - U_1: Q_{12} = k - 1: 1 - n: k - n.$

SATURATED AND SUPERHEATED STEAM.

Notation.

The symbols v, u, i, and s have the same significance as in the general notation; however, these symbols with a prime (v', s', etc.) refer to 1 lb. of water at the boiling temperature, and with a double prime (v'', u'', etc.) they refer to saturated steam. In addition, let

- r = latent heat, i.e., heat required to vaporize 1 lb, of liquid at given constant pressure and temperature.
- $\psi = Ap(v'' v') = \text{heat equivalent of external work required in vaporization.}$
- ρ = increase of energy during vaporization.
- x = quality of mixture, i.e., ratio of weight of steam present to total weight of mixture.
- c' = specific heat of water.

Fundamental Relations.

$$i'' = i' + r$$
. $u'' = u' + \rho$. $r = \rho + \psi$.

$$s' = \int_{401.6}^{T} c' \frac{dT}{T}. \quad s'' = s' + \frac{r}{T}.$$

$$\frac{\boldsymbol{r}}{\boldsymbol{T}} = A \left(v'' - v' \right) \frac{dv}{dt}$$
 (Clapeyron's relation.)

For a mixture of steam and water having a quality x,

$$i = i' + xr = i'' - (1 - x) r.$$

$$u = u'' - (1 - x) \rho.$$

$$s = s' + x \frac{r}{T} = s'' - (1 - x) \frac{r}{T}.$$

$$v = v' + x (v'' - v') = xv''$$
 approx.

Equations for Superheated Steam.

[In the following equations, take p in lb. per sq. inch.]

$$v = \frac{BT}{p} - (1 + 3ap^{\frac{1}{2}})\frac{m}{T^4} + 0.018.$$

$$c_p = 0.32 + 0.000126 T + \frac{23583}{T^2}$$

$$c_p = 0.32 + 0.000126 T + \frac{T^2}{T^2} + p \left(1 + 2 a p^{\frac{1}{2}}\right) \frac{C'}{T}$$

$$i = 0.32 T + 0.000063 T^{2} - \frac{23583}{T^{6}} - p \left(1 + 2 a p^{\frac{1}{2}}\right) \frac{C''}{T^{4}} + 948.54.$$

$$s = 0.73683 \log T + 0.000126 T - \frac{11792}{T^2}$$
$$-0.254 \log p - \left(1 + 2 \alpha p^{\frac{1}{2}}\right) \frac{C'''}{T^5}$$
$$-0.0807.$$

$$u = i - 0.1852 pv.$$

Constants in the preceding formulas:

$$\log B = \overline{1.77448}.$$
 $\log C' = 11.39361.$

$$\log 3 a = \overline{2.71000}$$
. $\log C'' = 10.79155$.

$$\log 2 a = \bar{2}.53391$$
. $\log C''' = 10.69464$.

 $\log m = 10.82500.$

Tables of the Properties of Steam.

Two tables of the properties of steam are included among the tables of this book. The first gives the important properties of saturated steam, while the second gives properties of superheated steam and also of mixtures of steam and water within certain limits. In this second table values of the entropy from 1.50 to 1.85 inclusive appear at the top of the page, and values of the pressures are given in the first column. By following a column the variation

of the volume v and the thermal head i during an adiabatic change of state is observed. The column designated by x gives the temperature of the superheated steam above the heavy dividing line and the quality of the mixture below this line.

Changes of State in Steam and Water Mixtures.

1. Isothermal or Constant Pressure. t = const. p = const.

$$W_{12} = p (V_2 - V_1) = Mp (v'' - v') (x_2 - x_1).$$

 $U_2 - U_1 = M\rho (x_2 - x_1).$ $Q_{12} = Mr (x_2 - x_1).$

2. Adiabatic. s = const.

$$s_{1}' + \frac{x_{1}r_{1}}{T_{1}} = s_{2}' + x_{2}\frac{r_{2}}{T_{2}}$$
 $Q_{12} = 0$.

$$W_{12} = (U_1 - U_2) J = JM [(i_1' + x_1\rho_1) - (i_2' + x_2\rho_2)].$$

3. Constant Volume. v = const.

$$x_1v_1'' = x_2v_2''$$
, or $x_2 = x_1 \frac{v_1''}{v_2''}$.
 $W_{12} = 0$. $Q_{12} = U_2 - U_1$
 $= M [(i_2' + x_2\rho_2) - (i_1' + x_1\rho_1)]$.

FLOW OF COMPRESSIBLE FLUIDS.

Fundamental Equations.

Let A denote the cross-section of the pipe or tube through which the fluid is flowing, w the mean velocity of the fluid across the section, and M the weight in lb. flowing through the section per second. If the flow is adiabatic, as may usually be assumed, the following equations apply.

1. Equation of continuity.

$$Aw = Mv$$
, or $\frac{A_1w_1}{v_1} = \frac{A_2w_2}{v_0}$.

2. Equation of energy.

$$Ji + \frac{w^2}{2g} = \text{const.}, \text{ or } Ji + \frac{w_1^2}{2g} = Ji_2 + \frac{w_2^2}{2g}.$$

The second equation may be expressed by the statement: the sum of the thermal head and the velocity head is a constant.

The two equations hold good for flow with friction. The effect of frictional resistances is to increase the thermal head Ji and decrease the velocity head $\frac{w^2}{2g}$ by an equal amount.

In the case of flow from a reservoir, as a steam boiler, the initial section A_1 may be considered inside the reservoir and the velocity w_1 may be neglected in comparison with the exit velocity w_2 . In this case the second equation becomes

$$\frac{w_2^2}{2 g} = J (i_1 - i_2)$$
or $w = \sqrt{2 g J} \sqrt{(i_1 - i_2)} = 223.7 \sqrt{(i_1 - i_2)}$.

For air, or other gases of similar nature,

$$J'(i_1-i_2)=\frac{k}{k-1}(p_1v_1-p_2v_2).$$

For steam, values of i are given in the steam tables.

Discharge Through Orifices.

Let p_1 denote the pressure in the reservoir, p_0 the pressure in the region into which the fluid discharges, and p_2 the pressure in the plane of the orifice, that is, at section A_2 . If p_0 is less than a certain critical value mp_1 , then p_2 takes

the value mp_1 , and the discharge is constant for all values of p_0 . If, however, p_0 is greater than

and values of p_0 . In however mp_1 , $p_2 = p_0$, and the discharge decreases as p_0 approaches p_1 . The value of m depends upon the properties of the fluid. For saturated or slightly wet steam m = 0.58; for superheated steam m = 0.55; and for air and similar gases m = 0.53.

Case 1. $p_0 \equiv mp_1$. Discharge is independent of p_0 .

 $p_2 = mp_1$. Take the flow as frictionless and find i_1 and i_2 corresponding to p_1 and p_2 from the second of the steam tables. Then

$$w_2 = 223.7 \sqrt{(i_1 - i_2)}$$
 and $M = \frac{Aw_2}{v_2}$.

For example, steam at 190 lb. pressure superheated to 450° flows through an orifice $\frac{3}{6}$ inch in diameter into a region in which the pressure is 60 lb. $p_2 = 0.55$ $p_1 = 104.5$ lb., and from the steam table $i_1 = 1241$, $i_2 = 1189$ B.t.u. and $v_2 = 4.26$ cu. ft. Also A = 0.1104 sq. in. = 0.000767 sq. ft.

$$w_2 = 223.7 \sqrt{1241 - 1189} = 1613$$
 ft. per sec.
 $M = \frac{0.000767 \times 1613}{4.26} = 0.29$ lb. per sec.,

or 17.4 lb. per min.

For saturated steam, the discharge may be calculated approximately by one of the following empirical formulas:

- 1. Napier's rule, $M = \frac{pA}{70}$.
- 2. Grashof's formula, $M = 0.0165 Ap^{0.97}$.
- 3. Rateau's formula,

$$M = \frac{pA}{1000} (16.367 - 0.96 \log p),$$

In these formulas p should be taken in lb. per sq. inch and A in square inches. Then M will give weight discharged per second.

For the discharge of air with $p_0 < 0.53 p_1$,

Fliegner's formula,

$$M=0.53\ \frac{pA}{\sqrt{T}}.$$

may be used.

Case 2. $p_0 > mp_1$. $p_2 = p_0$. The discharge depends upon p_0 and p_1 .

For steam, determine i_1 and i_0 , also v_0 , then

$$w_2 = 223.7 \ \sqrt{(i_1 - i_0)}, \quad M = \frac{Aw_2}{v_0}$$

For air the discharge in this case is given by the formula

$$M = 2.05 Ap_0 \sqrt{\frac{1}{T} \left(\frac{p_1}{p_0}\right)^{0.236}} \sqrt{\left(\frac{p_1}{p_0}\right)^{0.236} - 1}.$$

For small differences of pressure the discharge of air is given approximately by the formula

$$M = 1.1 A \sqrt{\frac{p_1}{T}(p_1 - p_0)}$$
.

Diverging Nozzles.

Diverging nozzles are used when the back pressure p_0 is less than the critical pressure $p_m = mp_1$. The pressure at the smallest sec-

tion, or throat, takes the value p_m , and if the nozzle is properly proportioned, the pressure at the end section A_2 is p_0 , the back pres-

sure; *i.e.*, $p_2 = p_0$. Taking $w_1 = 0$ in the reservoir, the second general equation gives

$$Ji_1 = Ji_m + \frac{w_m^2}{2a} = Ji_0 + \frac{w_0^2}{2a}$$
.

If the flow is adiabatic and frictionless, the entropy remains constant and the three thermal heads i_1 , i_m , and i_0 are found in the second steam table. The effective drop of head through the nozzle is $i_1 - i_0$. The effect of frictional resistances is to decrease this drop by y ($i_1 - i_0$), where y is a coefficient that may vary from 0.08 to 0.20 depending upon the size and smoothness of the nozzle.

,	Thermal Head at End Section.	Quality at End Section.	Volume at End Section.
Without friction. With friction.	$ \begin{array}{c} i_0 \\ i_0' = i_0 + \\ y(i_1 - i_0) \end{array} $	$x_0 = x_0 + \underbrace{y(i_1 - i_0)}_{r_0}$	$v_0 \\ v_0' = x_0' v_0''$

As an example, consider the design of a nozzle to discharge 0.7 lb. per second. The steam is initially at a pressure of 200 lb. per sq. in, and is superheated to 548° F.; and the back pressure is 40 lb. per sq. in. The coefficient y is taken as 0.14. From the second steam table, in the column s = 1.65, the following values are found: $i_1 = 1295$, i_m (for $p_m = 110$ lb.) = 1235, $i_0 =$ 1150, $v_m = 4.58$, $v_0 = 10.28$. The loss of jet energy due to friction is 0.14 (1295 - 1150) =20.3 B.t.u. Without friction x_0 at section A_0 is from the table 0.978, with friction it is 0.978 + 20.3= 1.00; hence the specific volume at sec-935.5 tion A_2 is 10.51. Using the fundamental equations, the following results are obtained:

Without friction With friction	$ \begin{array}{c c} i_1 \\ 1295 \\ \hline i_1 \\ 1295 \end{array} $	$\begin{bmatrix} i_m \\ 1235 \\ \hline i_0 \\ 1150 \\ 1170.3 \end{bmatrix}$	$\begin{vmatrix} i_1 - i_m \\ 60 \end{vmatrix}$ $\frac{i_1 - i_0}{145}$ 124.7	w_m 1733 w_0 2694 2498
	v_m 4.58			d_m (inch) 0.582
Without friction With friction	$x_0 \\ 0.978 \\ 1.00$	$\begin{vmatrix} v_0 \\ 10.28 \\ 10.51 \end{vmatrix}$	$A_0 \ ({ m sq.ft}) \ 0.00267 \ 0.00295$	$d_0 \ ({ m inch}) \ 0.700 \ 0.735$

Flow of Gases and Vapors in Mains.

The general equation of flow in pipes of circular cross-section, assuming that there is no transmission of heat is

$$v\,dp\,+\frac{cw^2}{d}\,dL=0,$$

in which d denotes the diameter and L the length of the pipe, and c is the coefficient of resistance.

If the drop of pressure is small, as is the case in short mains, this equation gives the approximate relation

$$p' = p_1 - p_2 = c \frac{w^2 L}{vd}$$
 (a)

When, on the other hand, the drop of pressure is considerable, integration of the general equation gives the relation

$$p_{1}^{2}-p_{2}^{2}=\frac{32}{T_{1}^{2}}c\frac{M^{2}BTL}{d^{5}},$$
 (b)

in which M denotes the weight of air flowing per second.

1. Flow of Steam. Since the drop of pressure is small formula (a) is used. The coefficient c is not constant but varies with the diameter of the pipe. Taking the diameter in inches, and the length L in feet formula (a) reduces finally to

$$p' = 0.000131 \left(1 + \frac{3.6}{d} \right) \frac{M^2 vL}{d^5}$$
or
$$M = 87.5 \left[\frac{p'd^5}{vL \left(1 + \frac{3.6}{d} \right)} \right]^{\frac{1}{2}}.$$

In these formulas M denotes the weight of steam flowing in pounds per minute, and v the volume of a pound of steam at the mean pressure p' in lb. per sq. inch.

2. Flow of Compressed Air. Let V denote the volume in cubic feet of free air at 70° F. and a pressure of 14.7 lb. per sq. in. flowing per minute. Since in the flow of compressed air, the drop of pressure is relatively large, formula (b) is used. By proper transformations it may be given the form

$$V = 3.061 \left[\frac{d^5 (p_1^2 - p_2^2)}{cL} \right]^{\frac{1}{2}},$$
 with $c = 0.003 \left(1 + \frac{3.6}{d} \right)$.

Here again d is to be taken in inches, L in feet, and p_1 , p_2 in pounds per square inch.

THE STEAM ENGINE.

Ideal Rankine Cycle.

Representing the changes of state on the *TS*-plane (see Fig.), the medium receives heat in the boiler and superheater during the processes 1-2-3; the line 3-4 represents adiabatic expansion in the cylinder; and the line 4-1 represents rejection of heat to the condenser.

Heat absorbed $= q_1 = i_3 - i_1$. Heat rejected $= q_2 = i_4 - i_1$. Heat available for work $= q_1 - q_2 = i_3 - i_4$.

Thermodynamic efficiency of cycle

$$=\eta_R=\frac{i_3-i_4}{i_3-i_1}\cdot$$

Steam required per H.P. hr. = $N_R = \frac{2546}{i_3 - i_4}$. B.t.u. required to give 1 H.P. hr.

$$=N_R(i_3-i_1)=\frac{2546}{\eta_R}.$$

Values of i_1 , i_3 , and i_4 are obtained directly from the steam tables. For example, steam is furnished at a pressure of 190 lb. per sq. in. superheated to 450° F., and the condenser pressure is 3 in. of mercury. Then

$$i_1 = 83 \text{ B.t.u.}$$
 $i_3 = 1241 \text{ B.t.u.}$ $i_4 = 913 \text{ B.t.u.}$

Heat available for work = 1241 - 913 = 328B.t.u.; steam consumption per H.P. hr. = $\frac{2546}{328}$ = 7.76 lb.; thermodynamic efficiency of cycle = $\frac{328}{1241 - 83} = 0.283$; B.t.u. required to produce 1 H.P. hr. = 7.76 (1241 - 83) = 8986 B.t.u.

Efficiency of the Actual Engine.

Under the same conditions of operation, the actual engine transforms a smaller amount of heat into work per pound of steam supplied than the ideal Rankine engine. Let q_R and q_a denote the heat transformed by the Rankine engine and the actual engine, respectively. The efficiency of the actual engine is defined by the relation

$$\eta = \frac{q_a}{q_B}$$

This efficiency ranges from 0.50 to 0.80 in steam engines and steam turbines.

Let N_a denote the actual steam consumption per H.P. hr. Then

$$N_{\alpha} = \frac{2546}{q_{\alpha}} = \frac{N_{\boldsymbol{R}}}{\eta}; \quad \text{or} \quad \eta = \frac{N_{\boldsymbol{R}}}{N_{\alpha}};$$

and the heat required to give 1 H.P. hr. is

$$N_a \left(i_3 - i_1 \right) = \frac{2546}{\eta \eta_R} \cdot$$

In the example preceding let the efficiency of the actual engine based on the ideal Rankine engine be 0.70; then the steam consumption is $7.76 \div 0.70 = 11.1$ lb. per H.P. hr., and the heat required per H.P. hr. is $8986 \div 0.70 = 12,837$ B.t.u.

STEAM BOILERS.

Let i_1 = thermal heat (heat of liquid) of water fed to boiler.

i₂ = thermal heat (total heat) of steam formed.

M = weight of water evaporated per hour.

 M_e = equivalent weight of water evaporated per hour from and at 212° F.

f = factor of evaporation.

H = rated horsepower of boiler.

By definition a boiler horsepower is equivalent to the evaporation of 34.5 lb. of water per hour from and at 212° F.

$$f = \frac{M_e}{M} = \frac{i_1 - i_2}{971.7}.$$

$$H = \frac{M_e}{34.5} = \frac{M(i_1 - i_2)}{33,520}.$$

$$M_e = fM.$$

CONDENSERS.

Steam enters the condenser at a known pressure p_1 and a quality x_1 , which is frequently assumed as 1. The thermal head of the entering steam is $i_1 = i_1' + x_1r_1$; that of the condensed steam leaving the condenser at the temperature t_2 is i_2' . If M lb. of condensing water is required and the temperature at entering and leaving are t_3 and t_4 , respectively, then

$$M = \frac{i_1' + x_1 r_1 - i_2'}{t_4 - t_3}.$$

INTERNAL COMBUSTION ENGINES.

The ideal cycles employed for internal combustion motors are the following:

- 1. Explosive, Otto.
- 2. Slow burning, non-explosive, Joule or Brayton, Diesel.

Otto Cycle.

Compression 1-2 and expansion 3-4 are assumed to be adiabatic. The line 2-3 represents the rapid heating at constant volume.

$$\frac{T_2}{T_1} = \frac{T_3}{T_4} = \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}} = \left(\frac{p_3}{p_4}\right)^{\frac{k-1}{k}} = \left(\frac{v_1}{v_2}\right)^{k-1}.$$

Heat absorbed = $Q_1 = Mc_v (T_3 - T_2)$.

If Q_1 is the heating value of the fuel and M the weight of the charge of fuel and air, the final temperature T_3 is

$$T_3 = T_2 + \frac{Q_1}{Mc_v}$$

The efficiency of the cycle is

$$\eta = 1 - \frac{T_1}{T_2} = 1 - \left(\frac{v_2}{v_1}\right)^{k-1} = 1 - \left(\frac{p_1}{p_2}\right)^{\frac{k-1}{k}}$$

Work of cycle =
$$W = \eta Q_1$$

= $JMc_v (T_3 - T_4 - T_2 + T_1)$.

Joule or Brayton Cycle.

The absorption of heat in the process 2-3 is at constant pressure.

$$\begin{aligned} \frac{T_2}{T_1} &= \frac{T_3}{T_4} = \left(\frac{v_1}{v_2}\right)^{k-1} \left(\frac{v_4}{v_5}\right)^{k-1} = \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}} \cdot \\ Q_1 &= Mc_p \left(T_3 - T_2\right); \ T_3 = T_2 + \frac{Q_1}{Mc_p} \cdot \end{aligned}$$

Efficiency =
$$\eta = 1 - \frac{T_1}{T_2} = 1 - \left(\frac{p_1}{p_2}\right)^{\frac{k-1}{k}}$$
.

Work of cycle = $\eta Q_1 = JMc_p (T_3 - T_2 - T_4 + T_1)$.

Diesel Cycle.

Air is compressed to a pressure of 500 lb. per sq. in. or more, and the fuel injected into this air burns at nearly constant pressure.

$$\frac{T_2}{T_1} = \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}} \cdot T_3 = T_2 + \frac{Q_1}{MC_p} \cdot \frac{v_3}{v_2} = \frac{T_3}{T_2} \cdot \frac{T_4}{T_3} = \left(\frac{p_4}{p_3}\right)^{\frac{k-1}{k}} \cdot$$

$$\begin{split} &\text{Efficiency} \,=\, \eta = 1 \,-\, \frac{T_4 \,-\, T_1}{k\, (T_3 \,-\, T_2)} \,\cdot \\ &\text{Work of cycle} \,=\, \\ &\eta Q_1 \,=\, JM\, [c_p\, (T_3 \,-\, T_2) \,-\, c_v\, (T_4 \,-\, T_1)]. \end{split}$$

AIR COMPRESSION.

Let V_1 = volume of free air entering compressor cylinder per stroke at pressure p_1 (atmospheric, or slightly lower).

 V_2 = volume of the same air when compressed to the higher pressure p_2 .

W =work required per strike.

H = net horsepower required to drive the compressor.

N = r.p.m. of double acting compressor.

The compression is assumed to follow the law $pv^n = \text{const.}$ The value of n lies between

1.2 and 14 depending upon the effectiveness of the water jacket. An average value is 1.3.

$$V_{2} = V_{1} \left(\frac{p_{1}}{p_{2}}\right)^{\frac{1}{n}}.$$

$$W = \frac{n}{n-1} (p_{2}V_{2} - p_{1}V_{1})$$

$$= \frac{n}{n-1} p_{1}V_{1} \left[\left(\frac{p_{2}}{p_{1}}\right)^{\frac{n-1}{n}} - 1\right].$$

$$(p_{2} \text{ and } p_{1} \text{ in lb. per sq. } foot.)$$

$$H = \frac{2NW}{33,000}.$$

If the compressor has no clearance the volume V_0 swept through by the piston is equal to V_1 . If there is clearance, the air caught in the clearance space expands from p_2 to p_1 and as a result $V_1 < V_0$. Let m = ratio of clearance volume to V_0 ; then

$$V_0 = \frac{V_1}{1 + m - m \left(\frac{p_2}{p_1}\right)^n}$$

Compound Compression.

If the air is compressed in two stages (1) from p_1 to an intermediate pressure p' (2) from p' to p_2 , then for minimum work of compression

$$p' = \sqrt{p_1 p_2}$$
and
$$W = \frac{2n}{n-1} p_1 V_1 \left[\left(\frac{p_2}{p_1} \right)^{\frac{n-1}{2n}} - 1 \right].$$

For compression in three stages with cooling between the stages, the proper intermediate pressures are

$$p' = \sqrt[3]{p_1^2 p_2}, \qquad p'' = \sqrt[3]{p_1 p_2^2},$$

and the work of compression per stroke is

$$W = \frac{3n}{n-1} p_1 V_1 \left[\left(\frac{p_2}{p_1} \right)^{\frac{n-1}{3n}} - 1 \right].$$

REFRIGERATION.

Air as the Medium.

Air is compressed adiabatically, as shown by 1-2, cooled at constant pressure (2-3), expanded adiabatically (3-4) in a separate expansion cylinder, and then passing through the brine absorbs heat from it, as represented by 4-1.

Let Q = heat absorbed from brine or coldroom per minute.

Q' = heat rejected to cooling water per minute.

M =weight of air circulated per minute.

H = horsepower (net) required.

 p_1 , p_2 = lower and higher pressures, respectively.

 $c_p =$ specific heat of air at constant pressure.

The temperatures T_1 and T_3 are fixed by the brine and cooling water; the temperatures T_4 and T_2 are obtained from the relation

$$\begin{split} \frac{T_2}{T_1} &= \frac{T_3}{T_4} = \left(\frac{p_2}{p_1}\right)^{\frac{k-1}{k}} \cdot \\ Q &= Mc_p \; (T_1 - T_4). \\ Q' &= Mc_p \; (T_2 - T_3). \end{split}$$

Work per minute =
$$J(Q'-Q)$$

= $JMc_p [(T_2-T_3)-(T_1-T_4)]$
= $JQ \frac{T_2-T_1}{T_1}$.
 $H = \frac{Q}{42.43} \frac{T_2-T_1}{T_1}$.

If N is the number of working strokes per minute, the required volume of the compressor cylinder (neglecting clearance) is

$$V_c = \frac{MBT_1}{Np_1}$$
;

that of the expansion cylinder is

$$V_e = \frac{MBT_4}{Np_1} \cdot$$

Vapor as the Medium.

Adiabatic compression (1-2) is followed by rejection of heat (2-3) to the cooling water

until the medium is a liquid (at point 3). Liquid passes through expansion valve dropping in pressure from p_2 to p_1 and attains state represented by point 4, with $i_3 = i_4$. Line 4-1 represents absorption of heat from brine at constant pressure p_1 . Using same notation as in preceding section,

$$Q = M (i_1 - i_4) = M (i_1 - i_3),$$

 $Q' = M (i_2 - i_3).$

Work required per minute = JM ($i_2 - i_1$).

$$H=\frac{M(i_2-i_1)}{42.43}.$$

Let v'' denote the volume of 1 lb. of the saturated vapor at the lower pressure p_1 ; and N the number of working strokes per minute; then the volume of the compressor cylinder is (neglecting clearance)

$$V_c = \frac{Mv''}{N}$$
.

If the cooling water enters at the temperature t_1 and leaves at temperature t_2 , the weight G required per minute is

$$G=\frac{M(i_2-i_3)}{t_2-t_1}.$$

Values of i_1 , i_2 , and i_3 are obtained from the tables of saturated and superheated ammonia or carbon dioxide.

ELECTRICAL ENGINEER-ING FORMULÆ.

COMPILED BY H. H. HIGBIE.

Professor of Electrical Engineering, University of Michigan.

NOTATION.

A = area, square centimeters.

 $A_m =$ cross-section area magnetic circuit, sq. cm.

B = flux density, maxwells per sq. cm., gausses.

 $B_m = \text{cyclic maximum flux density, gausses.}$

b =susceptance, mhos.

C = capacitance, farads.

 C_0 = capacitance to neutral, per mile of transmission line, farads.

d = distance, centimeters.

= diameter, mils.

E = e.m.f., volts, effective or square-root-mean-square value.

= unvarying voltage in d-c. circuit.

 E_{av} = average value of varying e.m.f., volts.

 $E_m = \text{maximum}$ instantaneous value of varying e.m.f.

 E_0 = volts to neutral, r.m.s. value.

 E_r = volts consumed in overcoming resistance.

 $E_{\sigma} = \text{e.m.f.}$ generated, volts.

 $E_t = \text{e.m.f.}$ between terminals, volts.

e = e.m.f. at any instant, volts.

F =force, dynes.

f =frequency, cycles per second.

F = magnetomotive force (m.m.f.), gilberts.

g = conductance, mhos.

 H = magnetizing force, field intensity, gausses in air, dynes force on unit pole.

I = current, amperes, effective or r.m.s. value.

= unvarying current in d-c. circuit.

 $I_t =$ current from terminals, amperes.

 $I_f = \text{current in (shunt) field, amperes.}$

 I_{α} = total current through armature, amperes.

i = current, amperes, at any instant.

i_c = charging current at any instant, amperes.

k =specific inductive capacity or dielectric constant.

K = constant.

L = self-inductance of electric circuit, henrys.

l = length.

 $l_m = \text{length magnetic circuit, centimeters.}$

 $l_{w} = \text{length of wire, centimeters.}$

M = mutual inductance, henrys, of two electrical circuits magnetically interlinked.

m = power factor.

= strength of magnet, in unit poles.

n = reactive factor.

= angular velocity, revolutions per second.

N =turns in coil or electrical circuit.

p = instantaneous power, watts.

= number of field poles.

P =average power, watts.

 P_{H} = power lost due to hysteresis, watts.

 P_{E} = power lost due to eddy-currents, watts.

P_r = power, watts, transformed into heat in overcoming resistance. Q, $q = \text{quantity of electricity, coulombs, amperes } \times \text{seconds.}$

R = resistance, ohms.

R = reluctance, oersteds.

r = radius.

s = number of parallel paths between armature terminals.

T = torque, pound-feet.

t =thickness, thousandths of inch, mils.

= temperature, degrees Centigrade.

= time elapsed, seconds.

r =velocity, centimeters per second.

V =volume, cubic inches.

w = weight, pounds.

 W_m = energy of magnetic field, watt-sec. or joules.

 $W_c = \text{energy stored}$ in condenser, wattseconds.

X = reactance, ohms.

y = admittance, mhos.

Z = impedance, ohms.

= number useful conductors on armature.

 α_0 = temp. coeff. of resistance, based on 0° C.

 ϵ = base of Naperian logarithms = 2.7183.

 $\eta = \text{efficiency}, \text{ ratio.}$

 $\theta = angle.$

= time-phase difference expressed in electrical degrees.

 $\mu = \text{permeability, ratio.}$

 $\rho_0 = \text{resistivity at 0° C., ohms per centimeter cube.}$

 Φ = magnetic flux, maxwells.

 ω = angular velocity, radians per second.

MAGNETIC FORCES AND FIELDS.

(a) Field due to a pole at a point.

Fig. 1.

 H_2 (at m_1 due to m_2) = $\frac{F}{m_1}$ = force (dynes), exerted on unit north pole.

$$F = \frac{m_1 m_2}{d^2} = m_1 H_2 = m_2 H_1.$$

(b) Field due to current in straight conductor.

Fig. 2.

H (at P due to i) =
$$\frac{i}{10 \cdot d} (\sin \theta_1 + \sin \theta_2)$$
.

Field (dynes force on unit north pole) at P is downward into paper if current flows toward right, and upward if current flows toward left. Field is circular and concentric with axis of conductor.

(c) Force on conductor due to current and field.

Conductor Fig. 4. Uniform Fig. 5. Conductor r. 3. alone.

field alone.

in field.

F (dynes on each centimeter length of wire) = $B \frac{i}{10}$, whence

Pounds force on wire

$$\begin{split} &= 22.5 \times 10^{-8} \cdot Bl_w i \\ &= \frac{5^{-}.1}{10^{8}} \, Bi \times \text{(length of wire, inches)}. \end{split}$$

This formula presumes that i is in direction at right angles to B. If the directions of i and B form an angle θ , the preceding expression for force must be multiplied by $\sin \theta$. This force is perpendicular to both i and B; it is in direction away from the side of the conductor where the field has been made more dense, and toward the side where the field has been made less dense (Fig. 5).

(d) Law of the magnetic circuit.

$$\Phi = \frac{\mathfrak{F}}{\mathfrak{R}} = \frac{0.4 \pi Ni}{l_m/\mu A_m}$$

$$B = \frac{\Phi}{A_m} = \mu H,$$

whence

$$H = 0.4 \, \pi \, \frac{Ni}{l_m} \cdot$$

and

Amp.-turns per inch length of magnetic circuit = $0.3132 \times \left(\frac{\text{maxwells per square inch}}{..}\right)$.

$$= 0.3132 \times \left(\frac{\mu}{\mu}\right)$$

See page 150 for magnetization curves.

MAGNETICALLY INDUCED ELECTRO-MOTIVE FORCE.

Fig. 6.

$$e \text{ (induced)} = \frac{Bvl_w}{10^8} = \frac{1}{10^8} \frac{d\Phi}{dt},$$

where Φ is the total maxwells linking the single turn of circuit shown. Direction of e is always such that force produced on current in same direction as e, by the field, would be in direction opposite to the velocity which produces e.

In general, if N turns are linked by a varying flux P maxwells, then

$$e \text{ (induced)} = \frac{1}{10^8} \frac{d}{dt} (\Phi N) = \frac{N}{10^8} \cdot \frac{d\Phi}{dt}$$

If a current i amperes flows, the conductor must move against a force $\left(\frac{Bil_w}{10}\right)$ dynes, whence

$$ei = \frac{Bvl_w}{10^8} \times \frac{10 \cdot F}{Bl_w} = \frac{Fv \text{ dyne-cm. per sec}}{10^7}$$
, or volts × amperes = watts

volts × amperes = watts

$$=\frac{\text{ergs per sec}}{10^7} = 746 \times \text{horse power.}$$

INDUCTANCE OF AN ELECTRIC CIRCUIT.

(a) General. An electric circuit has 1 henry inductance if 1 volt is induced in it when the current changes at rate of 1 ampere per second. A non-inductive circuit is one which builds no magnetic field when current flows. The induced e.m.f. must always oppose the change of current.

$$e \text{ (induced)} = -L \frac{di}{dt} = -\frac{1}{10^8} \frac{d}{dt} \text{ (ΦN$)},$$

$$L = \frac{1}{10^8} \frac{d}{di} \text{ (ΦN$)},$$

$$e \text{ (average)} = -\frac{1}{10^8} \times \frac{\Phi N}{t},$$

$$L \text{ (average)} = \frac{1}{10^8} \times \frac{\Phi N}{i},$$

where Φ is the flux produced by i, which links all of the turns N, and L is the average inductance within the current limits 0 to i, or flux limits 0 to Φ . If not all the flux links all the turns, but Φ_1 maxwells link N_1 turns, Φ_2 maxwells link N_2 turns, etc., we have

$$L ext{ (average)} = \frac{1}{10^8} \times \frac{\Phi_1 N_1 + \Phi_2 N_2 + \cdots}{i}$$

(b) Self-inductance of a transmission line in air, henrys per mile length of each single wire, is given by the equation

$$L_w = \left(0.08047 + 0.74113 \log_{10} \frac{d}{r}\right) \times 10^{-3},$$

where d is distance between centers of outgoing and return wires, and r is radius of wire, both in terms of same unit of length. Tables of inductance and reactance for transmission lines, found in Handbooks, are calculated from this formula; it applies also to each mile of each wire of a three-wire line if wires are all equidistant.

(c) Mutual inductance of two electric circuits.

$$egin{align} e_1 &= - \ M \ rac{di_2}{dt}, & ext{and} & e_2 &= - \ M \ rac{di_1}{dt}, \ M_{(av)} &= rac{1}{10^8} \, \cdot \, rac{\Phi_2 N_1}{i_2} = rac{1}{10^8} \, \cdot \, rac{\Phi_1 N_2}{i}, \ \end{array}$$

where i_1 amperes in one circuit cause Φ_1 maxwells to link with the N_2 turns of the other circuit, or i_2 amperes in the second circuit cause Φ_2 maxwells to link with the N_1 turns of the first circuit. If all of the flux produced by either of the two circuits links with all the turns of both circuits, we have:

$$L_1L_2=M^2.$$

ENERGY STORED IN MAGNETIC FIELD.

$$W_m = \frac{1}{2} Li^2 = \int_0^i Li \, di$$

gives the watt-seconds or joules of energy stored in magnetic field due to current i amperes in circuit having constant inductance L henrys.

 $W_{B} = \frac{B^2}{8\pi\mu} = \frac{\mu H^2}{8\pi}$

gives the ergs per cubic centimeter in a magnetic field of density B maxwells per square centimeter in a medium having constant permeability μ .

POWER DISSIPATED IN MAGNETIC CIRCUIT.

$$\begin{split} P_{H} &= K_{1}fB_{m}^{1.6} \ V = K_{2}fB_{m}^{1.6} \ w. \\ P_{E} &= K_{3}f^{2}B_{m}^{2}t^{2}V = K_{4}f^{2}B_{m}^{2}t^{2}w. \end{split}$$

Values of K, and of P_H or P_E for any assigned values of f, B_m , V, w and t may be calculated from data given on pages 150, 151. It is assumed that the flux varies harmonically with respect to time, and that it is uniformly distributed throughout the iron.

CONDENSERS AND ELECTROSTATICS.

(a) General.

$$C = \frac{q}{e}$$
, or $Q = Ce$.

C is in farads when q is in coulombs or ampere-seconds, and e is in volts.

$$i_c = \frac{dq}{dt} = C \frac{de}{dt}$$
, or $e = \frac{1}{C} \int i_c dt$.

(b) For several condensers in parallel, the equivalent total capacitance is

$$C_{eq} = C_1 + C_2 + C_3 + \cdots$$

(c) For several condensers in series, the equivalent total capacitance is given by the equation

$$\frac{1}{C_{co}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_2} + \cdots$$

(d) Capacitance of a parallel-plate condenser.

$$C = 0.08842 k \frac{A}{d} \times 10^{-12} \text{ farads}$$
$$= 0.08842 k \frac{A}{d} \times 10^{-6} \text{ microfarads,}$$

where d is the uniform distance, in centimeters, between oppositely charged surfaces each of A square centimeters area, and k is the specific inductive capacity of the dielectric between. It is assumed that d is small in comparison with dimensions of plates. Values of k for common insulating materials are given on page 151.

(e) Capacitance of single-conductor cable with grounded metal sheath.

$$C = \frac{0.03882 \, k}{\log_{10} (r_i/r_0)} \times 10^{-6} \text{ farads per mile,}$$

where r_0 is the external radius of the inner cylindrical conductor and r_i is the internal radius of the outer sheath, both in terms of same units. Total capacitance is directly proportional to length, since capacitances of successive miles are all in parallel.

(f) Capacitance to Neutral of each wire of a transmission line in air.

$$C_0 = \frac{0.03882}{\log_{10} (d/r)} \times 10^{-6}$$
 farads per mile,

where r is the radius of the wire and d is the distance between centers, both in terms of same units. It is assumed that d is large compared with r, and both small compared with distance to surrounding objects. For a two-wire line, capacitance between wires (per mile distance) is one-half the value given above, as the condensers from each wire to neutral

are in series. For three wires spaced equidistant (at vertices of equilateral triangle) as for three-phase line, the same formula gives capacitance to neutral per mile.

(g) Charging Current per mile of a transmission line in air.

$$I_c = 2 \pi f C_0 E_0,$$

where E_0 equals 0.50 times r.m.s. value of volts between line wires for a single-phase two-wire line, and 0.577 times r.m.s. volts between wires for a three-phase three-wire line. Harmonic e.m.f. and balanced voltages are assumed. I_c is r.m.s. amperes if E_0 is r.m.s. volts. Tables of charging current and line capacitance found in Handbooks are in accord with these formulæ.

(h) Energy stored in a condenser or in its dielectric.

$$W_c = \int Ce \, de = \frac{1}{2} \, Ce^2 = \frac{1}{2} \, \cdot \, \frac{Q^2}{C} = \frac{1}{2} \, Qe,$$

where W_c is the watt-seconds or joules required to raise condenser of C farads to a potential difference of e volts between terminals or plates, the charge being Q coulombs or ampereseconds.

CIRCUITS CARRYING DIRECT CURRENT (UNVARYING).

When a conductor carries an unvarying current, the e.m.f. between any two points a and b is directly and exactly proportional to the current. That is.

$$\frac{E}{I} = R = a \text{ constant}$$

= resistance of conductor ab.

If E is in volts and I in amperes, R is expressed as "ohms resistance." It is assumed that no e.m.f. is generated (as by battery or dynamo) between a and b.

(b) Resistance of a conductor. R is a constant for any given temperature, material and dimensions of conductor; it varies with each of these factors as indicated in the following equations.

 $R = R_0 (1 + \alpha_0 t)$ when dimensions and material of conductor remain unchanged.

 $R_0 = \rho_0 \frac{l}{A}$ when temperature is constant at 0° C.

 R_0 is ohms resistance at 0° C., and R is ohms for same conductor at t° C. α_0 , the temperature coefficient for resistance, equals 0.00427 for standard annealed copper and has practically the same value for most pure metals (including aluminum, and soft steel) although it varies greatly among alloys, non-metals and solutions. See Electrical an Engineering Handbook. is \mathbf{the} resistivity, ρ greatly with the nature and treatment of the conductor material; see page 152. l is the length of conductor and A its cross-section area in plane normal to direction of current flow, in same units used to determine ρ_0 .

$$R_0 = 6.0153 \, \rho_0 \, 10^6 \left(\frac{\text{length in feet}}{\text{section area in circular-mils}} \right)$$

One circular-mil is area of circle 0.001 inch diameter.

For round copper wires, at 20° C. or 68° F., the following relations form the basis for tables in Roebling's book "Wire in Electrical Construction":

Ohms per 1000 feet = $\frac{10371.2}{d^2}$.

Pounds per 1000 feet = $0.003027 d^2$.

 d^2 = section area in circ. mils = (diam. in inches \times 1000)².

Values of d for standard (Brown & Sharpe) gauge numbers are given on page 153.

(c) Total resistance of a series circuit.

Fig. 8.

$$R_s = R_1 + R_2 + R_3.$$

(d) Equivalent Resistance of a Parallel Circuit.

$$\frac{1}{R_n} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3},$$

assuming that none of the paths contains any source of e.m.f.

(e) Power lost in a conductor.

$$P_r = E_r I = IR \times I = I^2 R = \frac{E_r^2}{R},$$

where P_r is the watts transformed into heat in a conductor of R ohms resistance carrying I amperes. $E_r = IR$ is the volts consumed in overcoming resistance.

(f) Series circuits carrying direct current. Relations of current, e.m.f., and power.

Fig. 10,

Consider a generator G impressing an unvarying e.m.f. E_t upon a series circuit consisting of $R_1 + R_3$ ohms, and a battery (or a motor) having internal resistance R_2 ohms and a generated "back e.m.f." E_0 volts directed opposite to E_t (as indicated by dotted arrow). Then, if I represent the amperes flowing,

$$E_t - E_0 = I (R_1 + R_2 + R_3).$$

 $E_t = E_1 + E_2 + E_3$
 $= IR_1 + (E_0 + IR_2) + IR_3.$

 P_G = power output of generator = $E_t I$ watts. P_r = power transformed into heat in entire external circuit.

 $P_r = I^2 (R_1 + R_2 + R_3)$ watts.

 P_T = power transformed chemically in battery (or mechanically in motor) generating E_0 .

 $P_T = E_0 I$ watts.

 $P_2 = \text{power } input \text{ to battery (or motor).}$

 $P_2 = (E_0 + IR_2) I = E_0 I + I^2 R_2.$

If the connections are changed so that E_0 acts in same direction as E_t , then the sign of E_0 is reversed in the above equations:

$$E_t + E_0 = I (R_1 + R_2 + R_3).$$
 $P_2 = -(E_0 - IR_2) I = (E_0I - I^2R_2)$
watts output from generator of E_0 .

(g) Parallel circuits carrying direct current. Relations of current, e.m.f., and power.

8pp

Consider a generator G impressing an unvarying e.m.f. E_t upon a load having resistance R5 ohms and internal e.m.f. E5 volts, over line wires having resistances R_1 and R_4 ohms; let a battery whose generated e.m.f. (on open-circuit) is E_0 volts and internal resistance R_0 ohms be connected in parallel with G to this same load R_5 . Directions of E_0 and E_5 are indicated by dotted arrows.

Mark, as indicated, the directions in which currents I_1 , I_2 , I_5 in various parts of the circuit may flow; if the wrong direction happens to be chosen for any current, the algebraic solution of the following simultaneous equations will give negative value for that current. We may now write:

$$\begin{split} E_t - E_5 &= I_1 R_1 + I_5 R_5 + I_1 R_4 \\ \text{or} &\quad E_7 = E_5 + I_5 R_5 = E_t - I_1 \left(R_1 + R_4 \right), \\ \text{and} &\quad E_0 - E_5 = I_2 R_2 + I_2 R_0 + I_2 R_3 + I_5 R_5 \\ \text{or} &\quad E_7 = \left(E_0 - I_2 R_0 \right) - I_2 \left(R_2 + R_3 \right) \\ &\quad = E_6 - I_2 \left(R_2 + R_3 \right) \\ \text{and} &\quad I_1 + I_2 = I_5. \end{split}$$

Numerical values having been assigned to E_t , E_0 and E_5 in volts, and to all the resistances in ohms, we should be able to find corresponding values for I_1 , I_2 , I_3 by solving these equations.

- (h) Solution of Networks. As indicated in the preceding examples, the solution of any series-parallel arrangement of circuits, or network, depends on the application of two principles, commonly known as Kirchoff's Laws:
- (a) In any closed circuit the algebraic sum of the products of the current and resistance in each of the conductors in the circuit is equal to the electromotive force in the circuit. In applying this, account must be taken of the

relative direction of the e.m.f.'s and the currents in various parts of the circuit.

(b) The algebraic sum of the currents which meet at any point is zero; or, the sum of currents toward a juncture must be equal to the sum of currents away from that juncture.

DIRECT-CURRENT MACHINES.

(a) Electromotive force generated in the armature between terminals is

$$E_g = \frac{p\Phi Zn}{10^8 s}$$
 volts,

where the armature has altogether Z conductors on its outer surface arranged in s parallel circuits, and revolves at n revolutions per second in a field of p poles from each of which Φ maxwells enter the armature. If the dynamo operates as generator I is in same direction as E_g ; if it operates as motor, E_g is in opposition to I. Brushes are assumed to be on neutral points.

(b) Terminal voltage of a d-c. dynamo is

$$E_t = E_g \pm (R_a I_a + R_{se} I_{se} + R_{cp} I_{cp}),$$

where R_a , R_{se} , R_c are the resistances of armature, series field and commutating-poles, respectively, in ohms; and I_a , I_{se} , I_{cp} are the currents in the corresponding parts, amperes. The + sign is used if the dynamo operates as motor, the - sign if it operates as generator. For shunt-wound dynamo the $R_{se}I_{se}$ term is omitted, and if it has no commutating-poles omit the term $R_{cp}I_{cp}$.

(c) Torque of a dynamo is

$$T = \frac{0.1174 \ p\Phi Z I_a}{10^8 \ s} \text{ pound-feet,}$$

where T is the total torque magnetically developed on an armsture with Z surface conduc-

res

tors arranged in s parallel paths, due to a total current I_a amperes, when Φ maxwells enter the armature from each of p poles. The torque at pulley must be slightly greater than this in a generator, or slightly less in a motor, on account of friction (and magnetic losses if the dynamo is rotating).

(d) Speed of a motor is

$$n = \frac{10^8 E_{gS}}{p\Phi Z} = \frac{10^8 s \left(E_t - RI\right)}{p\Phi Z} \text{ rev. per sec.,}$$

where RI is the total resistance drop in the armature circuit across which E_t volts is impressed, including series field and commutating-pole winding if the motor has such.

(e) Efficiency and Losses in a d-c. dynamo.

For a Generator:

$$\eta = \frac{\text{watts output}}{\text{watts input}} = \frac{E_t I_t}{E_t I_t + P_f + P_{se} + P_{rp} + P_s}$$

For a Motor:

$$\eta = \frac{E_t I_t - P_f - P_{se} - P_{cp} - P_s}{E_t I_t}.$$

 $P_f = I_f^2 R_f = \text{heat loss in shunt field coils and rheostat.}$

 $P_{se} = I_{se}^2 R_{se}$ = heat loss in series field coils and regulating shunt.

 $P_{cp} = I_{cp}^2 R_{cp}$ = heat loss in commutating-pole winding.

 P_s = stray power, including hysteresis and eddy-current losses in armature core and in pole faces, and friction losses in bearings, brushes and windage.

GROWTH AND DECAY OF CURRENT IN INDUCTIVE CIRCUIT.

$$i = \frac{E}{R} \left(1 - \epsilon - \frac{Rt}{L} \right),\,$$

where i is the amperes flowing in a circuit having resistance R ohms and self-inductance L henrys

arranged in series, at an instant t seconds after an unvarying e.m.f. E volts has been applied. Current assumed to start from zero.

If the impressed e.m.f. E is removed from a circuit of resistance R ohms and self-inductance L henrys, when it is carrying a steady current $I = \frac{E}{R}$, and the circuit is closed through an additional resistance R_1 ohms, the current becomes i amperes at an instant t seconds after, where

$$i = I\epsilon - \frac{R+R_1}{L}t = \frac{E}{R}\epsilon - \frac{R+R_1}{L}t$$
.

The amount of e.m.f. generated in the coil at this instant is

$$e = L\frac{di}{dt} = i(R + R_1) = E\frac{R + R_1}{R}\epsilon^{-\frac{R + R_1}{L}t}.$$

General Equation for electric circuit having resistance R ohms, self-inductance L henrys, and capacitance C farads, all in series is

$$e = Ri + L\frac{di}{dt} + \frac{\int i\,dt}{C},$$

where e volts applied produces a current i amperes which is changing at the rate $\frac{di}{dt}$ amperes per second. This relation holds at every instant, for any mode of variation of e.m.f. or current.

HARMONIC ALTERNATING CURRENT.

A simple harmonic e.m.f. which completes f cycles per second has a value e volts at an instant t seconds after it has attained its maximum positive value E_m volts, where

$$e = E_m \cos 2\pi f t = E_m \cos \omega t$$
.

This e.m.f. will produce a simple harmonic current (i amperes) in any circuit having resistance R ohms, self-inductance L henrys, and capacitance C farads, where

$$i = I_m \cos(\omega t - \theta),$$

$$I_m = \frac{E_m}{\sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}},$$

$$= \frac{E_m}{\sqrt{R^2 + (X_L - X_C)^2}} = \frac{E_m}{Z},$$

$$\theta = \arctan\left(\frac{\omega L - \frac{1}{\omega C}\right)}{R} = \arccos\left(\frac{R}{Z}\right).$$

Effective or square-root-mean-square value of this e.m.f. is

$$E = \frac{E_m}{\sqrt{2}} = 0.707 E_m,$$

and of this current is

$$I = 0.707 I_m = \frac{E}{Z}.$$

Average value of this e.m.f. (during one half-cycle) is

$$E_{av} = \frac{2}{\pi} E_m = 0.636 E_m.$$

$$Form$$
-factor = $\frac{E_{effective}}{E_{average}} = \frac{0.707}{0.636}$
= 1.11 for harmonic e.m.f. or current.

Impedance =
$$Z = \frac{E}{I} = \sqrt{R^2 + X^2}$$
.
Reactance = $X = \left(2 \pi f L - \frac{1}{2 \pi f C}\right)$.

Power at any instant in a circuit where E (r.m.s.) volts produces I (r.m.s.) amperes, lagging (or leading) θ electrical degrees $\left(\text{or } \frac{\theta}{360} \text{ of } \frac{1}{f} \text{ seconds}\right)$ with respect to E, is

$$p \text{ (watts)} = ie = EI \cos \theta + EI \cos (4 \pi f t - \theta)$$
$$= E_m \cos \omega t \times I_m \cos (\omega t - \theta).$$

Average power in this circuit is

 $P = EI \cos \theta = \text{average of } p \text{ for complete cycle.}$

$$\begin{aligned} Power-factor &= \frac{P}{EI} = \frac{\text{power}}{\text{apparent power}}, \\ &= \cos \theta \text{ (when } e \text{ and } i \text{ are harmonic)} \\ &= \frac{R}{Z} = \frac{I^2 R}{IZ \cdot I}. \end{aligned}$$

Series Circuits carrying simple harmonic Alternating Current.

$$Z_1 = \sqrt{R_1^2 + X_1^2} = \frac{E_1}{1} Z_2 = \sqrt{R_2^2 + X_2^2} = \frac{E_2}{1} Z_3 = \sqrt{R_3^2 + X_3^2} = \frac{E_3}{1}$$
 E_1
 E_2
 E_3

Fig. 12.

$$R = R_1 + R_2 + R_3.$$

$$X = X_1 + X_2 + X_3.$$

$$Z = \sqrt{R^2 + X^2}.$$

$$I = \frac{E}{Z}.$$

Alt

Three units in series have e.m.f.'s E_1 , E_2 , E_3 (r.m.s. volts) respectively, power factors m_1 ,

 m_2 , m_3 , and reactive factors n_1 , n_2 , n_3 respectively, where

 $m = \cos \theta$

 $n = \sin \theta = \sqrt{1 - m^2}.$

All carry the same current, I (r.m.s. amperes).

Fig. 14.

Component of E in phase with I $= m_1 E_1 + m_2 E_2 +$ $m_3E_3=E_R.$

Component of E at 90° to I = $n_1E_1 + n_2E_2 +$ $n_3E_3=E_X.$

If I lags, nE is

positive; if I leads E, then nE is negative.

Total voltage = $E = \sqrt{E_{R^2} + E_{Y^2}}$.

Total power factor = $m = \cos \theta = \frac{E_R}{E}$.

Total reactive factor = $n = \sin \theta = \frac{E_X}{F}$.

Total power = $P = P_1 + P_2 + P_3 = m_1 E_1 I$ $+ m_2 E_2 I + m_3 E_3 I = mEI.$

Total reactive volt-amperes = $n_1 \Sigma_1 I$ + $n_2E_2I + n_3E_3I = nEI.$

Total apparent power = $\sqrt{(mEI)^2 + (nEI)^2}$ = EI (volt-amperes).

Parallel Circuits carrying simple harmonic Alternating Current.

Fig 15

7,

3).

Fig. 16.

Component of I_1 in phase with E equals

$$I_1 \times \frac{R_1}{Z_1} = \frac{R_1}{Z_1^2} \times E = g_1 E.$$

Component of I_2 in phase with E equals

$$I_2 \times \frac{R_2}{Z_2} = \frac{R_2}{Z_2^2} \times E = g_2 E.$$

Component of I in phase with E equals $(g_1 + g_2) E = gE$.

Component of I_1 at 90° to E equals

$$I_1 \times \frac{X_1}{Z_1} = \frac{X_1}{Z_1^2} \times E = b_1 E.$$

Component of I_2 at 90° to E equals

$$I_2 \times \frac{X_2}{Z_2} = \frac{X_2}{Z_2^2} \times E = b_2 E.$$

Component of I at 90° to E equals $(b_1 + b_2) E = bE.$

When the current leads, b is considered as positive, and when the current lags b is negative,

$$I = \sqrt{(gE)^2 + (bE)^2} = E \sqrt{g^2 + b^2} = yE.$$

Equivalent impedance

$$=Z=rac{E}{I}=rac{1}{y}=rac{1}{\sqrt{a^2+b^2}}$$

Equivalent resistance

$$=Z \cdot \frac{g}{y} = \frac{g}{g^2 + b^2} = R_{\text{eq.}}$$

Equivalent reactance

$$=Z\cdot\frac{b}{y}=\frac{b}{g^2+b^2}=X_{\rm eq}.$$

Instead of a simple combination of R, L and C, path No. 1 may be an induction motor taking I_1 amperes at E volts with power factor $m_1 = \frac{R_1}{Z_1}$, reactive factor $n_1 = \frac{X_1}{Z_1}$ (lagging); while path No. 2 may be an over-excited synchronous motor taking I_2 amperes at E volts with power

factor $m_2 = \frac{R_2}{Z_2}$, reactive factor $n_2 = \frac{X_2}{Z_2}$ (leading). In this case b_1 and b_2 would have opposite signs but inasmuch as both paths take in power, g will have the same sign in both cases.

Total power =
$$P = P_1 + P_2 = I_1^2 R_1 + I_2^2 R^2 = I^2 R_{eq}$$
.
= $m_1 E I_1 + m_2 E I_2 = g_1 E^2 + g_2 E^2$
= $m_1 E I_2 = g_1 E^2$

Total reactive volt-amperes

$$= I_1^2 X_1 + I_2^2 X_2 = I^2 X_{eq}.$$

= $n_1 E I_1 + n_2 E I_2 = b_1 E^2 + b_2 E^2$
= $n E I = b E^2$.

Total apparent power = $\sqrt{(mEI)^2 + (nEI)^2}$ = $E^2 \sqrt{g^2 + b^2}$ = EI (volt-amperes).

Total power factor =
$$m = \frac{m_1 I_1 + m_2 I_2}{I}$$
,
 $m = \frac{gE}{I} = \frac{g}{\sqrt{a^2 + b^2}}$.

Conductance, g, mhos. Susceptance, b, mhos. Admittance, y, mhos.

The significance and use of these three quantities, and the relation of each to R and X in either series or parallel circuits, should be evident from the preceding examples.

THREE-PHASE CIRCUITS.

(a) Star or Wye Connection.

Fig. 18.

For balanced or unbalanced condition:

Note. — The dots indicate that vectors, not arithmetic values, are added.

$$\begin{split} E_{AB} &= E_{AN} + E_{NB} = -E_{NA} + E_{NB} \\ E_{BC} &= E_{BN} + E_{NC} = -E_{NB} + E_{NC} \\ E_{CA} &= E_{CN} + E_{NA} = -E_{NC} + E_{NA} \\ I_A &= I_{NA}, \quad I_B = I_{NB}, \quad I_C = I_{NC} \\ I_{NA} &+ I_{NB} + I_{NC} = 0 \end{split}$$

(if no current flows in a neutral connection).

$$E_{AB} + E_{BC} + E_{CA} = 0.$$

 $\begin{array}{l} \text{Total power} = E_{NA}I_{NA}\cos\theta_{NA} + E_{NB}I_{NB}\\ \cos\theta_{NB} + E_{NC}I_{NC}\cos\theta_{NC}. \end{array}$

is:

1

V

also

The three phases are "balanced" when

$$\begin{split} I_A &= I_B = I_C. \\ E_{AB} &= E_{BC} = E_{CA} = \sqrt{3} \; E_{NA}. \\ E_{NA} &= E_{NB} = E_{NC}. \\ \theta_{NA} &= \theta_{NB} = \theta_{NC}. \end{split}$$

Phase angle between line voltage and phase voltage is 30° when phases are balanced.

Delta or Mesh Connection.

Esc Tec

Fig. 20.

For balanced or unbalanced condition:

$$I_A = I_{CA} + I_{BA} = I_{CA} - I_{AB}.$$
 $I_B = I_{AB} + I_{CB} = I_{AB} - I_{BC}.$
 $I_C = I_{BC} + I_{AC} = I_{BC} - I_{CA}.$

(For simplicity, only the first of these equations is illustrated in Fig. 20.)

$$\begin{aligned} E_{AB} + E_{BC} + E_{CA} &= 0. \\ \text{Total power} &= E_{AB} I_{AB} \cos \theta_{AB} + E_{BC} I_{BC} \\ \cos \theta_{BC} + E_{CA} I_{CA} \cos \theta_{CA} \end{aligned}$$

When the three phases are balanced, we have also:

$$\begin{split} \boldsymbol{I}_{A} &= \boldsymbol{I}_{B} = \boldsymbol{I}_{C} = \sqrt{3} \, \boldsymbol{I}_{AB}.\\ \boldsymbol{I}_{AB} &= \boldsymbol{I}_{BC} = \boldsymbol{I}_{CA}.\\ \boldsymbol{\theta}_{AB} &= \boldsymbol{\theta}_{BC} = \boldsymbol{\theta}_{CA}. \end{split}$$

Phase angle between line current and phase current is 30° when phases are balanced.

(c) Power in Three-phase Systems.

Fig. 21.

Se

Ur

and PSC

The

(XI

Let E_P , I_P and $\cos\theta_P$ be the e.m.f., current and power factor within each of the three phases, which may be connected either in wye or in delta; let E_L be the e.m.f. between line wires, I_L the current in each line wire, and $\cos\theta_L$ the power factor of the entire system. Then, for balanced system,

Total power =
$$3 E_{P} I_{P} \cos \theta_{P} = \sqrt{3} E_{L} I_{L} \cos \theta_{L}$$

$$\cos \theta_{L} = \frac{\text{total watts}}{\text{total volt-amperes}} = \cos \theta_{P}.$$

In the balanced system, the total power is unvarying — is the same at every instant.

Fig. 21 shows how to connect two identically similar wattmeters $(P_1 \text{ and } P_2)$ so that the alge-

braic sum of their indications equals the total power being transmitted over any three-wire system ABC (which may be three-phase). This is correct for any power factor, and for either balanced or unbalanced loads. For balanced loads the values P_1 and P_2 are equal at power factor 1.00; one of them becomes zero at power factor 0.50, and becomes negative for power factors lower than 0.50.

Power factor may be calculated from the wattmeter readingsif load is balanced, as follows:

$$\cos\theta = \frac{P_1 + P_2}{2\sqrt{P_{1}^2 - P_1 P_2 + P_2^2}}.$$

TRANSFORMERS: VOLTAGE AND CURRENT RATIOS

If practically all flux links both primary and secondary coils, as is usually the case in "constant voltage transformers," the ratio of primary turns in series to secondary turns in series is equal to the ratio of e.m.f. between primary terminals to e.m.f. between secondary terminals at zero load, or is equal to the inverse of the ratio of primary load current to secondary load current.

TRANSFORMERS: VOLTAGE REGULATION

With low-tension coils short-circuited, measure the "impedance volts" $(E_Z=ZI)$ necessary to impress upon high-tension winding to produce full-load current I_H in high-tension circuit, and measure also the (total) "impedance watts" P_{SC} then being supplied to the transformer. Then

$$(XI) = \sqrt{E_Z^2 - (RI)^2},$$
 and $(RI) = \frac{P_{SC}}{I_H}$

150 ELECTRICAL ENGINEERING

from which we draw the following diagram as for a simple series circuit:

Fig. 22.

wherein E' (= 100% of itself) represents rated high-tension voltage, $\cos \theta$ is the power factor of load between secondary terminals, (RI%) and (XI%) designate the e.m.f.'s RI and XI referred to above but expressed now as percentages of the rated high-tension voltage. From this diagram it follows that $(E_1\%)^2 =$

 $(100\cos\theta + RI\%)^2 + (100\sqrt{1-(\cos\theta)^2} + XI\%)^2$

Per cent voltage regulation of transformer = $E_1\% - 100$, wherein $(E_1\%)$ represents e.m.f. necessary to impress upon high-tension coils, as per cent of rated h-t e.m.f.

Transformers in parallel are treated as impedances in parallel, since E' must be the same for all that are paralleled, as also E_1 and ZI.

DISTRIBUTING LINES AND SHORT TRANSMISSIONS: REGULATION

The same diagram and equations given above for transformers should serve also for calculating voltage regulation of short transmissions (where the distribution of capacitance, inductance and leakance need not be considered). In this case E' represents the voltage required to be delivered at load end, I_H is total current in line to load, (RI%) is the resistance drop as percentage of load voltage E', (XI%) is the reactance drop

as per cent, $\cos \theta$ is the power factor of the load, $(E_1\%)$ is the e.m.f. necessary to impress at input end of line as per cent of load voltage. At zero load E' changes so as to equal E_1 , therefore the change of load voltage is the algebraic difference between E' and E_1 .

#### VI. CONVERSION FACTORS.

#### Angles.

1 rad.=57.2958 deg.=3437.75 min.=206,265 sec.

#### Areas.

- 1 sq. mile = 640 acres = 258.999 hectares.
- 1 hectare = 100 ares = 10,000 sq. meters = 2.471 acres.
- 1 acre = 10 sq. chains = 43,560 sq. ft.
- 1 sq. yd. = 9 sq. ft. = 0.836 sq. meter.
- 1 sq. meter = 10.764 sq. ft. = 1.196 sq. yd.

#### Densities.

- 1 lb. per cu. ft. = 16.018 kg. per cu. meter.
- 1 lb. per cu. in. = 27.680 g. per cu. cm.
- 1 kg. per cu. meter = 0.06243 lb. per cu. ft.
- 1 g. per cu. cm. = 0.03613 lb. per cu. in.

#### Discharge.

- 1 cu. ft. per sec.=448.9 gal. per min.=1.9835 acre-ft. per day.
- 1 acre-ft. per day = 0.5042 cu. ft. per sec.
- 1,000,000 gal. per day = 3.0689 acre-ft. per day = 1.547 cu. ft. per sec.
- 1 cu. ft. per sec. = 40 miner's inches.
- 1 miner's inch = 1.5 cu. ft. per min. = 11.22 gal. per min.
- 1 in. of rainfall per hr. = 1.008 cu. ft. per sec. per acre.

#### Energy.

- 1 ft-lb. = 1.356 joules or watt-sec.
- 1 joule =  $10^7$  ergs =  $10^7$  dyne-cm.
- 1 horse-power-hr. =  $1.98 \times 10^6$  ft-lb. = 0.7457 kw-hr. = 2544 Btu.
- 1 kw-hr.=1.341 horse-power-hr.=3411 Btu.= 2.654×10⁶ ft-lb.
- 1 Btu. = 778.4 ft-lb. = 0.252 kg-cal.
- 1 meter-kilogram = 7.233 ft-lb.

#### Force.

- 1 lb. = 0.4536 kg. = 444,822 dynes.
- 1 kg. = 2.2046 lb. = 980,665 dynes.
- 1,000,000 dynes=2.2481 lb.=1.020 kg.

#### Length.

- 1 mile=5280 ft.=80 chains=320 rods=1.6094 kilometers.
- 1 meter = 39.37 inches = 3.2808 ft. = 1.0936 yd.
- 1 in. = 2.54 cm. = 25.4 mm.
- 1 vd. = 0.9144 meter.
- 1 ft. = 30.48 cm. = 0.3048 meter.

#### Power.

- 1 horse-power = 33,000 ft-lb. per min. = 550 ft-lb. per sec.
- 1 horse-power = 0.7457 kw. = 0.7066 Btu. per sec.
- 1 kw. = 1.341 horse-power = 737.5 ft-lb. per sec.
- 1 horse-power = 1.0139 metric horse-power.

#### Pressure.

- 1 ft. of water = 62.4 lb. per sq. ft. = 0.433 lb. per sq. in.
- 1 in. of mercury = 1.134 ft. of water = 0.4912 lb. per sq. in.
- 1 atmosphere = 14.697 lb. per sq. in. = 33.9 ft. of water.
- 1 lb. per sq. ft. = 4.8824 kg. per sq. meter.
- 1 lb. per sq. in. = 0.07031 kg. per sq. cm.
- 1 kg. per sq. cm. = 14.223 lb. per sq. in. = 32.8 ft. of water.
- 1 ton per sq. ft. = 13.889 lb. per sq. in.

#### Temperature.

Deg. C. =  $(\text{deg. F.} - 32) \times 0.55556$ .

Deg. F. =  $(1.8 \times \text{deg. C.}) + 32$ .

#### Velocity.

- 1 rad. per sec. = 9.5496 rev. per min. = 0.15916 rev. per sec.
- 1 rev. per min. = 6.0000 deg. per sec.
- 1 ft. per sec. = 0.6818 miles per hr.
- 1 mile per hr. = 88 ft. per min. = 1.4667 ft. per sec.

#### Volume.

- 1 cu. yd. = 27 cu. ft. = 21.696 bushels.
- 1 cu. meter = 1000 liters = 1.308 cu. yds.
- 1 bu. = 8 gal. (dry) = 1.2445 cu. ft. = 2150.4 cu. in.
- 1 gal. (dry measure) = 1.1637 gal. (liquid measure).
- 1 cu. ft. = 7.481 gal. (liquid measure).

#### Weight.

- 1 lb. Avoir. = 1.2153 lb. Troy or Apoth.
- 1 lb. Avoir. = 16 oz. = 7000 grains = 0.4536 kg.
- 1 kg. = 2.2046 lb. Avoir.
- 1 short ton = 2000 lb. = 0.90718 metric ton.
- 1 long ton = 2240 lb. = 1.120 short tons.
- 1 metric ton = 1000 kg. = 2204.6 lb.

Moment of Inertia	43
Movement for Concentrated Loads	71
Moving Plates	96
Motion of a Point, Curvilinear	48
Napier's Rule for Flow of Steam	110
Networks	137
Neutral Axis, Equation of	59
Nozzles	111
Ohm's Law	133
Orifices and Jets	95
Otto Cycle	117
Parabola, The	18
Parabola, The Cubic	21
Paraboloids	22
Parallel Circuits:	
Impedance of	143
Resistance of	135
Solution of, Carrying Alternating Cur-	
rent 145	3, 144
Solution of, Carrying Direct Current .	
Dondalam	50

	PAGE
Permutations and Combinations	
Pipes, Flow in	97
ripes, Stresses III	03
Plane Triangles	11
Power	52
Power Factor:	
Loads in Parallel	145
Loads in Series	143
Three-phase System	148
Power for Loads in Series	143
Power for Loads in Parallel	145
Power for Three-phase Circuits	148
Power Lost in Resistance Power, Transmission of	135
Power, Transmission of	. 53,86
Precessional Rotation	51
Product of Inertia	44
Progression	3
Projectiles	
Proportion	
Quadratic Equations	
Radius of Curvature	25
Radius of Curvature for Beams	68
Radius of Gyration	44
Rankine Cycle	114
Rateau's Formula for Flow of Steam	110
Reactive Volt-amperes	1/2 1/5
Refrigeration, Air	121
Refrigeration with Vapor	121
Reinforced Concrete	122 124
Resistance of Conductors Resistance of Parallel Circuits	135
Resistance of Series Circuits Resistivity	
Riveted Joints	
Rotation	
Rotation, Precessional	01
Section Modulus	60
Series	4

INDEX	277
31(32112	PAGE
Series Circuits:	
Impedance of	142
Resistance of	135
Solution of, Carrying Alternating Cur-	
rent 142	, 143
Solution of, Carrying Direct Current	136
Shear, Diagonal	62
Shear, Vertical	65
Shearing Stresses	66
Sines and Cosines, Logarithmic	186
Sines and Cosines, Natural	222
Smith's (Hamilton) Formula for Weirs	94
Speed of D-C. Motor	139
Spheres	21
Spheres, Thin, Stresses in	63
Spherical Triangles	12
Spheroids	21
Spirals	20
Star Connection	146
Static Pressure	92
Statics	40
Steam Boilers	116
Steam, Changes of State of	108
Steam Engine	114
Steam, Fundamental Relations	106
	107
Steam Tables Explained	16
Stresses:	
Combined Stresses	84
Diagonal Stresses	62
	55
Direct Stresses	66, 84
Flexural Stresses	68
Stresses in Cylinders and Spheres	63
Struts	80
Submerged Weirs	94
Superheated Steam, Equations for	107
Thermal Head	103
Thermodynamics, Equations of	102
Susceptance	

## INDEX

	PAGE
Susceptance of Parallel Circuits	. 144
Tangents and Cotangents, Logarithmic	. 204
Tangents and Cotangents, Natural	. 240
Taylor's Theorem	. 25
Temperature Coefficient of Resistance.	. 134
Theorem of Three Moments	. 67
Three-phase Circuits	. 145
Top, Rotation of	. 51
Torsion	. 85
Transformation Formulæ	
Transformation of Coördinates	. 14
	53, 86
Triangles, Solution of	. 11
Trigonometry	. 8
Tube, Standard	
Velocity and Acceleration	
Velocity Head	-
Velocities, Relative, in Channels	
Velocities, Virtual	47
Volumes (See Sphere, Cone, etc.).	•
Weight of Copper Wires	. 134
Weirs	. 93
Work and Energy	. 52
WULL ALLU ELELEV	. 00
